Summer Semester 2013
George Mason University
Fairfax, VA
I dedicate this to my loving mother Parvaneh, my patient father Sirous, and my supportive brother Mehdi.
Acknowledgments

I would like to thank the many friends and supporters who have made this happen. First and foremost, I thank my advisor, Dr. Padmanabhan Seshaiyer, for his guidance and fatherly supports. My committee members, Drs. Thomas Wanner, David Walnut, Harbir Antil, and Andrei Draganescu, were of invaluable help. Finally, thanks go out to my fellow graduate students, specially Matthew Gerhart for his cute coding tips.

Abstract

MULTI-FIDELITY STOCHASTIC COLLOCATION

Maziar Raissi, PhD

George Mason University, 2013

Dissertation Director: Dr. Padmanabhan Seshaiyer

Over the last few years there have been dramatic advances in our understanding of mathematical and computational models of complex systems in the presence of uncertainty. This has led to a growth in the area of uncertainty quantification as well as the need to develop efficient, scalable, stable and convergent computational methods for solving differential equations with random inputs. Stochastic Galerkin methods based on polynomial chaos expansions have shown superiority to other non-sampling and many sampling techniques. However, for complicated governing equations numerical implementations of stochastic Galerkin methods can become non-trivial. On the other hand, Monte Carlo and other traditional sampling methods, are straightforward to implement. However, they do not offer as fast convergence rates as stochastic Galerkin. Other numerical approaches are the stochastic collocation (SC) methods, which inherit both, the ease of implementation of Monte Carlo and the robustness of stochastic Galerkin to a great deal. However, stochastic collocation and its powerful extensions, e.g. sparse grid stochastic collocation, can simply fail to handle more levels of complication. The seemingly innocent Burgers equation driven by Brownian motion is such an example. In this work we propose a novel enhancement to stochastic collocation methods using deterministic model reduction techniques that can handle this pathological example and hopefully other more complicated equations like
Stochastic Navier Stokes. Our numerical results show the efficiency of the proposed technique. We also perform a mathematically rigorous study of linear parabolic partial differential equations with random forcing terms. Justified by the truncated Karhunen-Loève expansions, the input data are assumed to be represented by a finite number of random variables. A rigorous convergence analysis of our method applied to parabolic partial differential equations with random forcing terms, supported by numerical results, shows that the proposed technique is not only reliable and robust but also very efficient.
Introduction

The effectiveness of stochastic partial differential equations (SPDEs) in modelling complicated phenomena is a well-known fact. One can name wave propagation [Pap71], diffusion through heterogeneous random media [Pap95], randomly forced Burgers and NavierStokes equations (see e.g [BT73, DPD03, KMS+97, MR04] and the references therein) as a couple of examples. Currently, Monte Carlo is by far the most widely used tool in simulating models driven by SPDEs. However, Monte Carlo simulations are generally very expensive. To meet this concern, methods based on the Fourier analysis with respect to the Gaussian (rather than Lebesgue) measure, have been investigated in recent decades. More specifically, Cameron–Martin version of the Wiener Chaos expansion (see, e.g. [CM47, HKPS93] and the references therein) is among the earlier efforts. Sometimes, the Wiener Chaos expansion (WCE for short) is also referred to as the Hermite polynomial chaos expansion. The term polynomial chaos was coined by Nobert Wiener [Wie38]. In Wieners work, Hermite polynomials served as an orthogonal basis. The validity of the approach was then proved in [CM47]. There is a long history of using WCE as well as other polynomial chaos expansions in problems in physics and engineering. See, e.g. [CC70, OB67, Cho71, Cho74], etc. Applications of the polynomial chaos to stochastic PDEs considered in the literature typically deal with stochastic input generated by a finite number of random variables (see, e.g. [SG02, GS03, XK03, ZL04]). This assumption is usually introduced either directly or via a representation of the stochastic input by a truncated Karhunen–Loève expansion. Stochastic finite element methods based on the Karhunen–Loève expansion and Hermite polynomial chaos expansion [GS03, SG02] have been developed by Ghanem and other authors. Karniadakis et al. generalized this idea to other types of randomness and
polynomials \cite{JSK02,XK03,XK02}. The stochastic finite element procedure often results in a set of coupled deterministic equations which requires additional effort to be solved. To resolve this issue, stochastic collocation (SC) method was introduced. In this method one repeatedly executes an established deterministic code on a prescribed node in the random space defined by the random inputs. The idea can be found in early works such as \cite{MH03,TPPM97}. In these works mostly tensor products of one-dimensional nodes (e.g., Gauss quadrature) are employed. Tensor product construction despite making mathematical analysis more accessible (cf. \cite{BNT07}) leads to the curse of dimensionality since the total number of nodes grows exponentially fast as the number of random parameters increases. In recent years we are experiencing a surge of interest in the high-order stochastic collocation approach following \cite{XH05}. The use of sparse grids from multivariate interpolation analysis, is a distinct feature of the work in \cite{XH05}. A sparse grid, being a subset of the full tensor grid, can retain many of the accuracy properties of the tensor grid. While keeping high-order accuracy, it can significantly reduce the number of nodes in higher random dimensions. Further reduction in the number of nodes was pursued in \cite{AA09,MZ09,NTW08b,NTW08a}. Applications of these numerical methods take a wide range. Here we mention some of the more representative works. It includes Burgers equation \cite{HLRZ06,XK04}, fluid dynamics \cite{KLM06,KNG+01,LMRN+02,LSWK07,XK03}, flow-structure interactions \cite{XLSK02}, hyperbolic problems \cite{CGH05,GX08,LSK06}, model construction and reduction \cite{DGRH07,GMPW05,GD06}, random domains with rough boundaries \cite{CK07,LSK07,XT06,XT06}, etc.

Along with an attempt to reduce the number of nodes used by sparse grid stochastic collocation, one can try to employ more efficient deterministic algorithms. The current trend is to repeatedly execute a full-scale underlying deterministic simulation on prescribed nodes in the random space. However, model reduction techniques can be employed to create a computationally cheap deterministic algorithm that can be used for most of the grid points. This way one can limit the employment of an established while computationally expensive algorithm to only a relatively small number of points. A related method is being used by K.
Willcox and her team but in the context of optimization [REWH08]. “Multifidelity”, which we also adopt, is the term they employed in their work. For a tractable demonstration of our method we consider linear parabolic partial differential equations with random forcing terms. We show that our method dramatically decreases the computational cost of sparse grid stochastic collocation methods. The idea of the method is very simple. For each point in the stochastic parameter domain we search to see if the resulting deterministic problem is already solved using a high fidelity (accurate but computationally expensive) algorithm, e.g. Backward Euler Finite Elements method, for a sufficiently close problem. If yes, we use the solution to the nearby problem to create POD (Proper Orthogonal Decomposition) basis functions. These are highly relevant global basis functions. We then employ POD-Galerkin method, a low fidelity algorithm (less accurate but computationally cheap), to solve the original problem. We provide a rigorous convergence analysis for our proposed method applied to linear parabolic partial differential equations. It is shown by numerical examples that the results of numerical computation are consistent with theoretical conclusions.

We also consider the Stochastic Burgers equation studied in [HLRZ06] to test our method against a serious while still tractable problem. We believe that the non-linear nature of the Burgers equation with the extra complexity of Brownian motion, makes this equation a proper test for our method. The regular repetitive execution of the full-scale underlying high-fidelity deterministic algorithm for the sparse grid stochastic collocation simply fails for this equation. This equation is also studied in [HLRZ06] using Wiener Chaos expansion. For the deterministic Burgers equation resulting from stochastic collocation samples, we are going to use a high fidelity algorithm called “group finite element” (GFE) and a low fidelity algorithm called “group proper orthogonal decomposition” (Group POD). These two methods are discussed in [DS10]. The GFE method, also known as product approximation, is a finite element (FE) technique for certain types of non-linear partial differential equations. It expresses the non-linear terms of a PDE in a grouped form. As a result, spatial discretization of non-linear terms is computed only once before integration. Therefore, a substantial reduction in computational cost is achieved [CGMSS81, Fle83, Roa98]. Experiments with
the GFE method have indicated an increase in economy and a slight increase in the nodal accuracy compared to FE solutions of the unsteady Burgers equations and many other problems [CGMSS81, Fle83, SF92]. Although theoretical results exist for other problems [CGMSS81, SSA84, CLZ89, DD75, LTZW89, Mur86, TOU90], we are unaware of convergence theory for the GFE applied to Burgers equation. The computational advantage of the GFE method over the conventional FE method for two and three dimensional Burgers equations and viscous compressible flows is demonstrated in [Fle83, SF92]. As for the group POD method, we use the projection of grouped non-linear terms onto a set of global basis functions. This projection onto global basis functions further reduces the cost of simulation due to symmetry in the non-linear terms. Reduced order modelling, using proper orthogonal decompositions (POD) along with Galerkin projection, for fluid flows has seen extensive applications studied in [Sir87, CAM+88, HLB98, Fah01, ILD00, KV01, KV02, HY02, RCM04, Cam05]. Proper orthogonal decomposition (POD) was introduce in Pearson [Pea01] and Hotelling [Hot33]. Since the work of Pearson and Hotelling, many have studied or used POD in a range of fields such as oceanography [BV97], fluid mechanics [Sir87, HLB98], system feedback control [Rav00, ABK01, AK01, KBTB02, AK04, LT05], and system modeling [Fah01, KV02, RCM04, HY05].

In an attempt to increase the accuracy of our method, we employ local improvement techniques for reduced-order models using sensitivity analysis of the proper orthogonal decomposition (see [HBP09, BB97]). A serious limitation of proper orthogonal decomposition basis is that while it accurately represents the flow data used to generate it, it may not be as accurate when applied off-design. To mitigate this issue, one should update the basis before applying it to solve a nearby problem.
Chapter 1: Multi-fidelity Stochastic Collocation Method
applied to Stochastic Burgers Equation

Our objective in this work is to demonstrate how sparse grid stochastic collocation method

can be enhanced using deterministic model reduction techniques. To simplify the presenta-

tion while employing a serious test, we study the stochastic Burgers equation. It is a well

known fact that the deterministic Burger’s equation is not a good model of turbulence. It
does not display chaotic behaviour; all solutions converge to a unique stationary solution as
time goes to infinity, even in the presence of a forcing term in the right hand side. However,
several authors (see e.g. [CAM+88,CTMK93,Jen69,HY75,KPZ86]) have suggested to use
the Stochastic Burgers equation with random forcing term as a simple model for turbulence
and to study the dynamics of interferences.

1.1 Stochastic Burgers - A tractable while serious test

The Stochastic Burgers equation studied in this work is given by,

\[ u_t + \frac{1}{2}(u^2)_{xx} = \mu u_{xx} + \sigma(x)\dot{W}(t), \] (1.1)

\((t, x) \in (0, T] \times [0, 1], u(0, x) = u_0(x), u(t, 0) = u(t, 1) = 0, \) where \(W(t)\) is a Brownian motion
and \(u_0 \in L_2([0, 1])\) is a deterministic initial condition. If \(\|u_0\|_{L_2} < \infty\) and \(\|\sigma\|_{L_2} < \infty\), it
is known (see, e.g [DPDT94]) that (1.1) has a unique square integrable solution. If \(u\) is
the solution of equation (1.1), then \(u\) is not only a function of \(t\) and \(x\), but it is also a
function of the Brownian motion path \(W^t_0 = \{W(s), 0 \leq s \leq t\}. \) In order to approximate
the Brownian motion with a finite number of independent and identically distributed (iid)
standard normal random variables, we let \( \{ h_k, k = 1, 2, \ldots \} \) be an arbitrary orthonormal basis in \( L_2([0, t]) \) and define \( \xi_k := \int_0^t h_k(s) dW(s) \), for \( k \in \{1, 2, \ldots \} \). It can be shown that \( \xi_k \) are iid Gaussian random variables. It is a standard fact that we can expand \( W(s) \) as

\[
W(s) = \int_0^t \chi_{[0,s]}(\tau)dW(\tau) = \sum_{k=1}^{\infty} \xi_k \int_0^s h_k(\tau)d\tau,
\]

where \( \chi_{[0,s]}(\tau) \) is the characteristic function of the interval \([0, s]\). Note that

\[
\chi_{[0,s]}(\tau) = \sum_{k=1}^{\infty} c_k h_k(\tau),
\]

where \( c_k = \int_0^t \chi_{[0,s]}(\tau)h_k(\tau)d\tau = \int_0^s h_k(\tau)d\tau \). If \( \{ h_k, k = 1, 2, \ldots \} \) are chosen as Haar wavelets, then expansion (1.2) is exactly the Levy-Ciesielski construction [McK69] of Brownian motion. Therefore we can view a solution \( u \) of (1.1) as a function of \( x, t \) and \( \xi = (\xi_1, \xi_2, \ldots) \). We also know that expansion (1.2) converges in the mean square sense (i.e., \( E[W(s) - \sum_{k=1}^{d} \xi_k \int_0^s h_k(\tau)d\tau|^2 \) goes to zero as \( d \to \infty \) uniformly for \( s \leq t \)). Our first step is to truncate expansion (1.2) at some point \( d \) to get

\[
\frac{1}{2} u_t + \frac{1}{2} (u^2)_x = \mu u_{xx} + \sigma(x) \sum_{k=1}^{d} \xi_k h_k(t).
\]

In the following, we are seeking an approximation to a random field

\[
u_d(\xi; t, x) \in C^\infty(\mathbb{R}^d; L_2([0, T]; W([0, 1])))
\]

which satisfies equation (1.3) along with the initial and boundary conditions of problem (1.1), where \( \xi = (\xi_1, \xi_2, \ldots, \xi_d) \) and \( W([0, 1]) \) is a Banach space of functions \( v : [0, 1] \to \mathbb{R} \).
to be later specified. Let us assume that the random vector $\xi$ has $\rho(\xi)$ (which is simply the multiplication of probability densities of $d$ standard normal variables) as its joint probability density. We are also interested in approximating expectation and higher moments $E[u_d^k] \in L^2([0,T]; W([0,1])), k = 1, 2, \ldots$ of the solution which are given by

$$E[u_d^k](t, x) = \int_{\mathbb{R}^d} u_d^k(\xi; t, x)\rho(\xi)d\xi, \ k \in \{1, 2, \ldots\}. \quad (1.4)$$

For simplicity, we are overloading the symbol $\xi$ to denote both a random vector and its realizations. For each fixed $\xi$, equation (1.3) can be written as,

$$u_t + \frac{1}{2}(u^2)_x = \mu u_{xx} + f_d(t, x), \quad (1.5)$$

where $f_d(t, x) = \sigma(x) \sum_{k=1}^d \xi_k h_k(t)$. Whether we are using Monte Carlo or Stochastic Collocation, in order to solve the stochastic equation (1.3), we need to solve the deterministic equation (1.5) many times for different values of $\xi$. In the following, we specify the high fidelity and the low fidelity algorithms that we will employ to solve equation (1.5).

1.2 GFE as a high-fidelity deterministic algorithm

A standard finite element approximation to the solution $u_d(t, x)$ of equation (1.5) can be written as $u_{d,N}(t, x) = \sum_{j=1}^N \alpha_j(t) \beta_j(x)$, where $\{\beta_j(x), j = 1, \ldots, N\}$ are $N$ piecewise linear finite element basis functions, and each $\alpha_j(t)$ is an unknown function of time. We also define $W_N([0,1]) := \text{span}\{\beta_j, j = 1, \ldots, N\}$. The basis functions are chosen according to a computational grid on the domain $[0,1]$ with $\{x_n, n = 0, \ldots, N + 1\}$ as its set of nodes, in a way that $\beta_j(x_n) = \delta_{j,n}$, where $\delta_{j,n}$ is the Kronecker delta and $j, n = 1, \ldots, N$. Note that $u_{d,N}^2(t, x_n) = \sum_{j=1}^N \alpha_j^2(t) \beta_j(x_n)$. This motivates us to approximate $u_d^2(t, x)$ by
\[ \sum_{j=1}^{N} \alpha_j^2(t) \beta_j(x) \]. Use of the weak form of (1.5) and the approximations for \( u_d \) and \( u_d^2 \) results in the following differential equations.

\[
M \dot{\alpha} = -\mu A \alpha - \frac{1}{2} G(\alpha) + V(t), \quad (1.6)
\]

\[
\alpha(0) = \alpha_0 = [(u_0, \beta_i)]_{i=1}^{N},
\]

where \( G(\alpha) = N[\text{diag}(\alpha)] \alpha, [N]_{ij} = (\beta_j', \beta_i), [M]_{ij} = (\beta_j, \beta_i), [A]_{ij} = (\beta_j', \beta_i'), [V(t)]_i = (f_d(t, .), \beta_i) \) and \( (f, g) = \int_0^1 f(x)g(x)dx \) is the standard \( L_2([0,1]) \) inner product. We are using \( \dot{y} \) and \( y' \) to denote the derivatives with respect to time and space, respectively. This algorithm is called group finite elements (GFE). A detailed study of this method can be found in [DS10]. We employ this algorithm only once for \( \xi = 0 \) which results in \( f_d \equiv 0 \). Note that if more accurate results are needed, this algorithm can be employed at more points in the stochastic space. Details of this improvement will be provided later in the next chapters. For now, it suffices to use it only once.

### 1.3 Group POD as a low-fidelity deterministic algorithm

Solution to equations (1.6), with \( V(t) \equiv 0 \), gives an approximate solution \( w(t, x) \) to (1.5), with \( f_d(t, x) \equiv 0 \). Let \( \{w(t_i,.), i = 1, \ldots, S\} \) be a set of \( S \) “snapshots”, where

\[
t_1 < t_2 < \ldots < t_S
\]

are equally spaced points of time in the interval \([0, T]\). The correlation matrix \( K \) of the data set \( \{w(t_i,.), i = 1, \ldots, S\} \) can be defined as

\[
K := \left(\frac{1}{S}(w_i, w_j)\right)_{i,j=1}^{S} \quad (1.7)
\]
where \( w_i = w(t_i, \cdot) \), \( i = 1, \ldots, S \). Let \( \{ \lambda_k, Z_k \} \) denote the eigenvalues and the corresponding normalized eigenvectors of \( K \). Define \( Z \) to be the matrix \([Z_1| \ldots |Z_S]\). The POD basis functions \( \{ \psi_k \}_{k=1}^S \) are given as

\[
\psi_k = \frac{1}{\sqrt{S \lambda_k}} \sum_{i=1}^{S} [Z]_{i,k} w_i, \quad k = 1, \ldots, S. \tag{1.8}
\]

Let the solution \( u_d \) to (1.5) be written as

\[
u_d(t, x) = U(x) + v_d(t, x) \tag{1.9}
\]

where \( U(x) := \frac{1}{S} \sum_{i=1}^{S} w(t_i, x) \). Therefore, using (1.5), we obtain that \( v_d \) satisfies

\[
u_t + \frac{1}{2} (v^2)_x - \mu (v_{xx} + U'') + UU' + Uv_x + vu' = f_d, \tag{1.10}
\]

\((t, x) \in (0,T] \times [0,1], v(0, x) = v_0(x) = u_0(x) - U(x), v(t, 0) = v(t, 1) = 0.\)

Let the POD approximation of \( v_d(t, x) \) be given by \( v_{d,p}(t, x) = \sum_{j=1}^{M} a_j(t) \psi_j(x) \), where \( \psi_j \) is a POD basis function, and \( a_j(t) \) is an unknown function of time. Note that \( M \) is the dimension of the POD basis. Furthermore, let \( v_d^2(t, x) \) be approximated by \( \sum_{j=1}^{M} F_j(a) \psi_j(x) \), with \( F_j(a) \) as an unknown function of \( a(t) = [a_j(t)]_{j=1}^{M} \). The projection of equation (1.10) onto the POD set \( \Psi = \{ \psi_k \}_{k=1}^{M} \) results in the variational problem of finding \( v \in L_2([0,T]; W_{N,M}([0,1])) \), where \( W_{N,M}([0,1]) := \text{span}\{ \Psi \} \), such that

\[
(v_t, \psi_i) + \frac{1}{2} ((v^2)_x, \psi_i) + (UU', \psi_i) + \ldots + \mu (v_x + U', \psi_i') + (Uv_x + U'v, \psi_i) = (f_d, \psi_i), \tag{1.11}
\]
and \((v(0, \cdot), \psi_i) = (v_\theta, \psi_i)\), for \(i = 1, \ldots, M\). When the POD approximations for \(v_d\) and \(v^2_d\) are substituted into equation (1.11), we obtain the system of ordinary differential equations

\[
M \dot{a} = -Aa - \frac{1}{2} N_p F(a) - V(t), \quad (1.12)
\]

\[
a(0) = a_0 = [(v_\theta, \psi_i)]_{i=1}^M,
\]

where \([N_p]_{ij} = (\psi'_j, \psi_i), [M]_{ij} = (\psi_j, \psi_i), [A]_{ij} = \mu(\psi'_j, \psi'_i) + (U \psi'_j + U' \psi_j, \psi_i), [V]_i = (-f_d + UU', \psi_i) + \mu(U', \psi'_i), \) and \(F(a) = [F_i]_{i=1}^M\) is determined as given below. At the grid points \(x_n, n = 1, \ldots, N\) we want to have

\[
\sum_{j=1}^M F_j(a) \psi_j(x_n) = \left( \sum_{j=1}^M a_j(t) \psi_j(x_n) \right)^2. \quad (1.13)
\]

Let \(\gamma_{nj} = \psi_j(x_n)\), then,

\[
\sum_{j=1}^M F_j(a) \gamma_{nj} = \left( \sum_{j=1}^M a_j(t) \gamma_{nj} \right)^2 = \sum_{j,\ell=1}^M \gamma_{nj} \gamma_{n\ell} a_j a_\ell \quad (1.14)
\]

Since \(\gamma_{nj} \gamma_{n\ell} = \gamma_{n\ell} \gamma_{nj}\), for \(j \neq \ell\) we can avoid computing \(\gamma_{nj} \gamma_{n\ell}\) twice by writing

\[
\sum_{j,\ell=1}^M \gamma_{nj} \gamma_{n\ell} a_j a_\ell = \hat{\gamma}_n \hat{a} \quad (1.15)
\]

where \(\hat{\gamma}_n\) is a \(1 \times \frac{1}{2}(M^2 + M)\) vector given as

\[
\hat{\gamma}_n := [\gamma_{n1} \gamma_{n1}, 2\gamma_{n1} \gamma_{n2}, \ldots, 2\gamma_{n1} \gamma_{nM}, \gamma_{n2} \gamma_{n2}, 2\gamma_{n2} \gamma_{n3}, \ldots, 2\gamma_{n2} \gamma_{nM}, \ldots, \gamma_{nM} \gamma_{nM}]
\]
and the $\frac{1}{2}(M^2 + M) \times 1$ vector $\hat{a}$ is

$$\hat{a} := [a_1 a_1, a_1 a_2, \ldots, a_1 a_M, a_2 a_2, a_2 a_3, \ldots, a_2 a_M, \ldots, a_M a_M]^T.$$ 

We may write (1.14) in the matrix form as

$$\Gamma F(a) = \hat{\Gamma} \hat{a}$$

(1.16)

where the $N \times M$ matrix $\Gamma$ is given by

$$\Gamma = \left[ \begin{array}{cccc} \gamma_{11} & \gamma_{12} & \cdots & \gamma_{1M} \\ \vdots & \vdots & \ddots & \vdots \\ \gamma_{N1} & \gamma_{N2} & \cdots & \gamma_{NM} \end{array} \right]$$

(1.17)

and $\hat{\Gamma}$ is the $N \times \frac{1}{2}(M^2 + M)$ matrix $[\hat{\gamma}_i]_{i=1}^N$. Equation (1.16) normally has no solution, since $M$ is generally chosen to be less than $N$. However, similar to the method used in [DS10], one can directly approximate the product $N_p F(a)$ by $\Gamma^T N \Gamma F(a)$, where $N$ is the matrix used in (1.6). We can finally approximate $N_p F(a)$ by

$$N_p F(a) \approx \hat{N} \hat{a},$$

(1.18)

where $\hat{N}$ is the $M \times \frac{1}{2}(M^2 + M)$ matrix given by $\hat{N} = \Gamma^T N \hat{\Gamma}$. With this, problem (1.12) takes the form

$$M \dot{\hat{a}} = -Aa - \hat{N} \hat{a} - V(t),$$

(1.19)

$$a(0) = a_0 = [(v_0, \psi_i)]_{i=1}^M.$$ 

11
This model is then solved for \( a(t) \) to give an approximation \( v_{d,p}(t,x) = \sum_{j=1}^{M} a_j(t)\psi_j(x) \) of \( v_d(t,x) \). Therefore, according to (1.9), \( u_d(t,x) \) is approximated by \( U(x) + v_{d,p}(t,x) \). The above algorithm called group proper orthogonal decomposition (group POD) is studied in detail in [DS10]. We will employ this algorithm for other sample values of \( \hat{\xi} \) in the stochastic space.

1.4 Multi-fidelity Stochastic Collocation

We are finally in a position to demonstrate the multi-fidelity stochastic collocation method. Our aim is to approximate the solution of (1.3) in the space \( V_{N,p} = L_2([0,T];W_N([0,1])) \otimes P_p(\mathbb{R}^d) \), where \( W_N([0,1]) = \text{span}\{\beta_j\} \) is the finite element space, and \( P_p(\mathbb{R}^d) \) is the span of tensor product polynomials with degree at most \( p = (p_1,\ldots,p_d) \). The procedure for approximating the solution of (1.3) is divided into two parts:

1. Use the Group POD method to solve problem (1.5) at \( \hat{\xi} \in \mathbb{R}^d \) and get the solution \( u_d(\hat{\xi},t,x) \).

2. Collocate on zeros of suitable orthogonal polynomials and build the interpolated solution \( u_{d,p} \in V_{N,p} \) using

\[
u_{d,p}(\hat{\xi},t,x) = I_p u_d(\hat{\xi},t,x) = \sum_{j_1=1}^{p_1+1} \cdots \sum_{j_d=1}^{p_d+1} u_d(\xi_1,\ldots,\xi_d,t,x)(l_{j_1}(\hat{\xi}) \otimes \cdots \otimes l_{j_d}(\hat{\xi})), \tag{1.20}
\]

where the functions \( \{l_{jk}\}_{k=1}^d \) can be taken as Lagrange polynomials. Using this formula, as described in [BNT07], mean value and variance of \( u_d \) can also be easily approximated.
1.4.1 Generalization to Sparse Grids

Here, we give a short description of the isotropic Smolyak algorithm. More detailed information can be found in [BNR00, NTW08b]. Assume \( p_1 = p_2 = \cdots = p_d = p \). For \( d = 1 \), let \( \{I_{1,1}\}_{i=1,2,...} \) be a sequence of interpolation operators given by equation (1.20). Define \( \Delta_0 = I_{1,0} = 0 \) and \( \Delta_i = I_{1,i} - I_{1,i-1} \). Now for \( d > 1 \), let

\[
\mathcal{A}(q,d) = \sum_{0 \leq i_1 + i_2 + \cdots + i_d \leq q} \Delta_{i_1} \otimes \cdots \otimes \Delta_{i_d} \tag{1.21}
\]

where \( q \) is a non-negative integer. \( \mathcal{A}(q,d) \) is the Smolyak operator, and \( q \) is known as the sparse grid level. Now instead of (1.20), \( \mathcal{A}(q,d)u_d(\hat{\xi},t,x) \) can be used to approximate the solution \( u_d \) of (1.3). This way one reduces the number of grid points on which the deterministic algorithms should be employed.

1.5 Numerical results

In the following numerical experiment, we let \( T = 1.0, \; u_0(x) = (e^{5\cos(5\pi x)} - 3)\sin(\pi x), \; \sigma(x) = 0.01, \) and \( \mu = \frac{1}{200} \). We discretize time into 50 steps, and divide the spatial domain into 64 intervals. We solve the problem by the Monte Carlo method and compare the results with the solution of our algorithm. We use the Clenshaw-Curtis abscissas (see [CC60]) as collocation points. These abscissas are the extrema of Chebyshev polynomials. We project the Brownian motion in \([0,T]\) on the trigonometric basis functions \( h_k(t) \) in \( L_2([0,T]) \) given by

\[
h_1(t) = \frac{1}{\sqrt{T}}, \quad h_k(t) = \sqrt{\frac{2}{T}} \cos \left( \frac{(k-1)\pi t}{T} \right), \quad k \in \{2,3,\ldots\}. \tag{1.22}
\]

For small values of \( d \) in (1.3), say \( d = 2 \), and sparse grid level 6, sparse grid stochastic collocation with the full employment of the expensive high-fidelity GFE provides similar results to when sparse grid stochastic collocation is used with the cheap low-fidelity group.
POD algorithm. The results, using 10 POD basis functions, are summarized in Figure 1.1 and in Table 1.1. In this table Monte Carlo method is the reference point.

Standard deviations of the two methods is shown in Figure 1.2. Note that we are only using a single point in the stochastic parameter space to generate POD basis functions. We are also performing no types of improvement to the POD basis functions. The issue brought
Table 1.1: Comparison of the errors of the two methods.

<table>

up in Figure 1.2 can be simply dealt with by either increasing the number of times that the high fidelity algorithm is employed, or by local improvements to POD basis functions (see Chapter 3), or both. Numerical results section of Chapter 3 illustrates the effect these improvements.

![Comparison of Methods](image)

Figure 1.2: Standard Deviation of the solution given at final time $T = 1.0$ when $d = 2$ for sparse grid level 6.

Even for such a low dimension of $d = 2$, the enhanced version of the algorithm using the POD method shows an increase in speed of over 10 times when the number of spatial points is increased to 512. The results, using 10 POD basis functions, are summarized in Table 1.2.
For larger values of $d$, say $d = 4$, however, the regular sparse grid stochastic collocation algorithm is not at all efficient due to the huge amount of computations it needs to perform. The enhanced version of the sparse grid stochastic collocation seems to provide a cure in this case. Using 10 POD basis functions, as the sparse grid level changes from 7 to 9, we get the convergence pattern presented in Figure 1.3. These results compared with the solution of Monte-Carlo are illustrated in this figure. This time we are discretizing the spacial domain into 128 intervals. The stochastic collocation with POD for levels 8 and 9 compares well with the Monte Carlo solution. Level 7 of the sparse grid is where convergence is first taking effect.

Execution times and the errors in expected values and second moments, when the sparse grid level changes from 7 to 9, are given in Table 1.3. For the sparse grid part of our code we modified the Matlab toolbox developed in [KW05, Kli07] to benefit from the parallel features of Matlab programming language.

Remark 1.1. It may be noted that stochastic collocation methods and consequently our multi-fidelity method are most effective in small noise regimes. This remark holds true for
Remark 1.2. For the eigenvalues and eigenvectors computations in (1.8) we are using Matlab’s “eigs” command. This is efficient if the size of the correlation matrix introduced in equation (1.7) is relatively small. For more complicated systems, Matlab’s “svds” command might be employed as well. This remark holds true for next chapters as well.
Chapter 2: Multi-fidelity Stochastic Collocation Method
applied to Parabolic PDEs with Random Input Data

Up to this point we were employing the high fidelity algorithm only once. The idea is to
utilize this algorithm more often and consequently increase the accuracy. In order to be able
to provide rigorous analysis of our proposed method we start the study of linear parabolic
partial differential equations in this chapter.

2.1 Problem definition

Let \( D \subset \mathbb{R}^2 \) be a bounded, connected and polygonal domain and \((\Omega, \mathcal{F}, P)\) denote a complete
probability space with sample space \( \Omega \), which corresponds to the set of all possible outcomes.
\( \mathcal{F} \) is the \( \sigma \)-algebra of events, and \( P : \mathcal{F} \rightarrow [0, 1] \) is the probability measure. In this section,
we consider the stochastic linear parabolic initial-boundary value problem: find a random
field \( u : [0, T] \times \overline{D} \times \Omega \rightarrow \mathbb{R} \), such that \( P \)-almost surely the following equations hold:

\[
\begin{align*}
\partial_t u(t, x, \omega) - \Delta u(t, x, \omega) &= f(t, x, \omega) \quad \text{in} \quad (0, T) \times D \times \Omega, \\
u(t, x, \omega) &= 0 \quad \text{on} \quad (0, T) \times \partial D \times \Omega, \\
u(0, x, \omega) &= 0 \quad \text{on} \quad D \times \Omega.
\end{align*}
\]

In order to guarantee the existence and uniqueness of the solution of (2.1), we assume that
the random forcing field \( f : [0, T] \times \overline{D} \times \Omega \ni (t, x, \omega) \mapsto f(t, x, \omega) \in \mathbb{R} \) satisfies:

\[
\int_0^T \int_D f^2(t, x, \omega)dxdt < +\infty \quad P\text{-a.e. in } \Omega. \quad (2.2)
\]
Following [BNT07] and inspired by the truncated KL expansion [Loe77], we make the assumption that the random field \( f \) depends on a finite number of independent random variables. More specifically,

\[
f(t, x, \omega) = f(t, x, y(\omega)) \quad \text{on} \quad [0, T] \times \mathcal{D} \times \Omega,
\]

where \( y(\omega) = (y_1(\omega), \ldots, y_r(\omega)) \) and \( r \in \mathbb{N}_+ \). Let us define the space,

\[
L^2_P(\Omega) := \{ y = (y_1, y_2, \ldots, y_r)^T : \sum_{n=1}^r \int_{\Omega} |y_n(\omega)|^2 dP(\omega) < \infty \},
\]

where \( y \) denotes an \( r \)-dimensional random vector over \((\Omega, \mathcal{F}, P)\). We also define the Hilbert space,

\[
V := L^2(0, T; H^1_0(D)) \otimes L^2_P(\Omega),
\]

with the inner product \((.,.)_V : V \times V \to \mathbb{R} \) given by:

\[
(u, v)_V = \int_0^T \int_D \mathbb{E}[\nabla u(t, x, \omega) \cdot \nabla v(t, x, \omega)] dx dt.
\]

A function \( u \in V \) is called a \textit{weak solution} of problem (2.1) if:

\[
\int_D \mathbb{E}[\partial_t uv] dx + \int_D \mathbb{E}[\nabla u \cdot \nabla v] dx = \int_D \mathbb{E}[fv] dx,
\]

\[
\forall v \in H^1_0(D) \otimes L^2_P(\Omega) \quad \text{and} \quad \forall t \in (0, T],
\]

and \( P \)-almost surely \( u(0, x, \omega) = 0 \). The existence and uniqueness of the solution of problem (2.4) is a direct consequence of assumption (2.2) on \( f \); see [Eva].

Let \( \Gamma_n = y_n(\Omega) \) denote the image of the random variable \( y_n \), for \( n = 1, \ldots, r \), and
\[ \Gamma = \prod_{n=1}^{r} \Gamma_n. \] We also assume that the distribution measure of \( y(\omega) \) is absolutely continuous with respect to the Lebesgue measure. Thus, there exists a joint density function \( \rho : \Gamma \to \mathbb{R}_+ \) for \( y = (y_1, \ldots, y_r) \). Hence, we can use \( (\Gamma, B^r, \rho dy) \) instead of \( (\Omega, \mathcal{F}, P) \), where \( B^r \) is the \( r \)-dimensional Borel space. Analogous to the definitions of \( L^2_P(\Omega) \) and \( V \) we can define

\[ L^2_\rho(\Gamma) := \{ y \in \Gamma : \int_\Gamma ||y||^2 \rho dy < \infty \}, \]

and

\[ V_\rho = L^2(0,T; H^1_0(D)) \otimes L^2_\rho(\Gamma), \]

with inner product

\[ (u, v)_{V_\rho} = \int_{\Gamma} (u(y), v(y))L^2(0,T;H^1_0(D))\rho dy. \]

where

\[ (u(y), v(y))_{L^2(0,T;H^1_0(D))} = \int_0^T \int_D \nabla u(t,x,y). \nabla v(t,x,y) dx dt. \]

The weak solution \( u \in V \) of problem (2.1), using the finite dimensional noise assumption (2.3), is of the form \( u(t,x,\omega) = u(t,x,y_1(\omega),\ldots,y_r(\omega)) \). Therefore, the weak formulation (2.4) can be equivalently expressed as finding \( u \in V_\rho \) such that \( \rho \)-almost everywhere in \( \Gamma \), \( u(0,x,y) = 0 \), and

\[ \int_\Gamma \int_D \partial_t uv dx \rho dy + \int_\Gamma \int_D \nabla u. \nabla v dx \rho dy = \int_\Gamma \int_D fv dx \rho dy, \]

\[ \forall v \in H^1_0(D) \otimes L^2_\rho(\Gamma) \text{ and } \forall t \in (0,T]. \]

For each fixed \( t \in (0,T] \), the solution \( u \) to (2.5) can be viewed as a mapping \( u : \Gamma \to H^1_0(D) \). In order to emphasize the dependence on the variable \( y \), we use the notations \( u(y) \) and \( f(y) \). Hence, we achieve the following equivalent settings: find \( u(y) \in H^1_0(D) \) such that \( \rho \)-almost
everywhere in $\Gamma$, $u(0, x, y) = 0$, and

$$
\int_D \partial_t u(y)vdx + \int_D \nabla u(y) \cdot \nabla vdx = \int_D f(y)vdx,
$$

(2.6)

$\forall v \in H^1_0(D)$ and $\forall t \in (0, T]$, $\rho$-a.e. in $\Gamma$.

Note that there may exist a $\rho dy$-zero measure set $\mathcal{N}_\rho \subset \Gamma$ in which (2.6) is not satisfied. Therefore, from a computational perspective, if a point $y \in \mathcal{N}_\rho$ is chosen, the resulting solution of (2.6) is not the true solution of the original equation. However, the computation of the moments of the solution does not suffer from this disadvantage.

### 2.2 Multi-fidelity Collocation method

In this section, we apply our multi-fidelity stochastic collocation method to the weak form (2.6). Let $V_{\rho, h}$ be a finite dimensional subspace of $V_\rho$ given by $V_{\rho, h} = L^2(0, T; H_h(D)) \otimes P_p(\Gamma)$, where $H_h(D) \subset H^1_0(D)$ is a standard finite element space and $P_p(\Gamma) \subset L^2_\rho(\Gamma)$ is the span of tensor product polynomials with degree at most $p = (p_1, \ldots, p_r)$. The goal is to find a numerical approximation to the solution of (2.6) in the finite dimensional subspace $V_{\rho, h}$. Choose $\eta > 0$ to be a small real number. The procedure for solving (2.6) is divided into two parts:

1. Fix $y \in \Gamma$, and search the $\eta$-neighbourhood $B_\eta(y) \subset \Gamma$ of $y$. If problem (2.6) is not already solved by the finite element method for any nearby problem with $y' \in B_\eta(y)$, solve problem (2.6) using a regular backward Euler finite element method at $y$ and let $y' = y$. In contrast, if equation (2.6) is already solved using the finite element method for some points in $B_\eta(y)$, choose the closest one to $y$ and call it $y'$. In either case, use the solution at $y' \in B_\eta(y)$ to find a small number $d \in \mathbb{N}_+$ of suitable orthonormal basis functions $\{\psi_j(y')\}_{j=1}^d \subset H_h(D)$ using proper orthogonal decomposition (POD) method. Now use Galerkin projection on to the subspace $X^d(y') = \text{span}\{\psi_j(y')\}_{j=1}^d$
to find
\[ \{u^m_d(y)\}_{m=1}^N \subset X^d(y') \subset H_h(D), \]
such that
\[ (u^m_d, v_d) + k(\nabla u^m_d, \nabla v_d) = k(f^m(y), v_d) + (u^{m-1}_d, v_d), \quad \forall v_d \in X^d(y'), \quad m = 1, \ldots, N, \]
and \( u^0_d = 0 \), where \( N \in \mathbb{N}_+ \) is the number of time steps, and \( k = T/N \) denotes the
time step increments. It is worth mentioning that \((\cdot, \cdot)\) denotes the \( L^2 \)-inner product.
Note that we are employing a backward Euler scheme to discretize time.

2. Collocate (2.7) on zeros of suitable orthogonal polynomials and build the interpolated
 discrete solution
\[ \{u^m_{d,p}\}_{m=1}^N \subset H_h(D) \otimes P_p(\Gamma), \]
using
\[ u^m_{d,p}(x, y) = \mathcal{I}_p u^m_d(x, y) = \]
\[ \sum_{j_1=1}^{p_1+1} \cdots \sum_{j_r=1}^{p_r+1} u^m_d(x, y_{j_1}, \ldots, y_{j_r})(l_{j_1}(y) \otimes \cdots \otimes l_{j_r}(y)), \quad m = 1, \ldots, N, \]
where the functions \( \{l_{j_k}\}_{k=1}^r \) can be taken as Lagrange polynomials. Using this formula, as
described in [BNT07], mean value and variance of \( u \) can also be easily approximated.

2.2.1 Proper Orthogonal Decomposition

In this section, we choose a fixed \( y' \in B_\eta(y) \subset \Gamma \) and drop the dependence of equation
(2.6) on \( y' \), for notational conveniences. Therefore, we consider the problem of finding
\[ w \in H_0^1(D) \text{ such that:} \]
\[ (w_t, v) + (\nabla w, \nabla v) = (g, v), \quad \forall v \in H_0^1(D), \quad (2.10) \]

and \( w(x,0) = 0 \), for all \( x \in D \). Note that \( g = f(y') \). Let \( t_m = mk, k = 0,\ldots,N \), where \( k \) denotes the time step increments. Assume \( \Sigma_h \) to be a uniformly regular family of triangulation of \( \overline{D} \) (see [Tho97,Cia78]). The finite element space is taken as

\[ \mathcal{H}_h(D) = \{ v_h \in H_0^1(D) \cap C^0(D) : v_h|_K \in P_s(K), \forall K \in \Sigma_h \}, \]

where \( s \in \mathbb{N}_+ \) and \( P_s(K) \) is the space of polynomials of degree \( \leq s \) on \( K \). Write \( w^m(x) = w(x, t_m) \), and let \( w_h^m \) denote the fully discrete approximation of \( w \) resulting from solving the problem of finding \( w_h^m \in \mathcal{H}_h(D) \) such that \( w_h^0(x) = 0 \) and for \( m = 1,\ldots,N \),

\[ (w_h^m, v_h) + k(\nabla w_h^m, \nabla v_h) = k(g^m, v_h) + (w_h^{m-1}, v_h), \quad (2.11) \]
\[ \forall v_h \in \mathcal{H}_h(D), \quad m = 1,\ldots,N. \]

It is easy to prove that problem (2.11) has a unique solution \( w_h^m \in \mathcal{H}_h(D) \), provided that \( g^m \in L^2(D) \) (see [Tho97]). One can also show that if \( w_t \in H^{s+1}(D) \) and \( w_{tt} \in L^2(D) \), the following error estimates hold:

\[ ||w^m - w_h^m||_0 \leq Ch^{s+1} \int_0^{t_m} ||w_t||_{s+1} dt + Ck \int_0^{t_m} ||w_{tt}||_0 dt, \quad m = 1,\ldots,N, \quad (2.12) \]

where \( ||.||_s \) denotes the \( H^s(D) \)-norm and \( C \) indicates a positive constant independent of the spatial and temporal mesh sizes, possibly different at distinct occurrences.
For the so-called snapshots $U_i := w_{h}^{m_i} \in H_h(D)$, $i = 1, \ldots, \ell$, where

$$1 \leq m_1 < m_2 < \cdots < m_\ell \leq N,$$

let

$$V = \text{span}\{U_1, \ldots, U_\ell\}.$$

Assume at least one of $U_i$ is non-zero, and let $\{\psi_j\}_{j=1}^{l}$ be an orthonormal basis of $V$ with $l = \text{dim} V$. Therefore, for each $U_i \in V$ we will have:

$$U_i = \sum_{j=1}^{l} (U_i, \psi_j)_{H^1_0(D)} \psi_j,$$

where $(U_i, \psi_j)_{H^1_0(D)} = (\nabla w_{h}^{m_i}, \nabla \psi_j)$.

**Definition 2.1.** The POD method consists of finding an orthonormal basis $\psi_j$ ($j = 1, 2, \ldots, d$) such that for every $d = 1, \ldots, l$, the following problem is solved

$$\min_{\{\psi_j\}_{j=1}^{d}} \frac{1}{l} \sum_{i=1}^{\ell} \|U_i - \sum_{j=1}^{d} (U_i, \psi_j)_{H^1_0(D)} \psi_j\|_{H^1_0(D)}^2.$$

A solution $\{\psi_j\}_{j=1}^{d}$ of this minimization problem is known as a POD basis of rank $d$.

Let us introduce the correlation matrix $K = (K_{ij})_{i,j=1}^{\ell} \in \mathbb{R}^{\ell \times \ell}$ given by

$$K_{ij} = \frac{1}{\ell} (U_i, U_j)_{H^1_0(D)}.$$

The following proposition (see [Sir87, KV01, KV02]) solves problem (2.14).

**Proposition 2.2.** Let $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_\ell > 0$ denote the positive eigenvalues of $K$ and $v_1, v_2, \ldots, v_\ell$ the associated orthonormal eigenvectors. Then a POD basis of rank $d \leq \ell$ is
given by

$$
\psi_i = \frac{1}{\sqrt{\lambda_i}} \sum_{j=1}^{\ell} (v_i)_j U_j, \quad i = 1, \ldots, d,
$$

(2.16)

where $(v_i)_j$ denotes the $j$-th component of the eigenvector $v_i$. Furthermore, the following error formula holds:

$$
\frac{1}{\ell} \sum_{i=1}^{\ell} \|U_i - \sum_{j=1}^{d} (U_i, \psi_j)_{H^1_h(D)} \psi_j\|_{H^1_h(D)}^2 = \sum_{j=d+1}^{l} \lambda_j.
$$

(2.17)

One can immediately notice the similarities between equation (2.17) and a truncated singular value decomposition.

Let $X^d := \text{span}\{\psi_1, \psi_2, \ldots, \psi_d\}$, and consider the problem of finding $w^m_d \in X^d \subset H_h(D)$ such that $w^0_d(x) = 0$ and for $m = 1, \ldots, N$,

$$
(w^m_d, v_d) + k(\nabla w^m_d, \nabla v_d) = k(g^m, v_d) + (w^{m-1}_d, v_d),
$$

\[(2.18)\]

\[\forall v_d \in X^d \subset H_h(D), \quad m = 1, \ldots, N.\]

Remark 2.1. If $\Sigma_h$ is a uniformly regular triangulation and $H_h(D)$ is the space of piecewise linear functions, the total degrees of freedom for problem (2.11) is $N_h$, where $N_h$ is the number of vertices of triangles in $\Sigma_h$, while the total of degrees of freedom for problem (2.18) is $d$ (where $d \ll l \ll \ell \ll N_h$).

The following proposition, proved in [LCSY09], gives us an error estimate on the solution of problem (2.18).

Proposition 2.3. If $w^m_h \in H_h(D)$ is the solution of problem (2.11), $w^m_d \in X^d \subset H_h(D)$ is the solution of problem (2.18), $k = O(h)$, $\ell^2 = O(N)$, and snapshots are equably taken,
then for \( m = 1, 2, \ldots, N \), the following estimates hold:

\[
\| w^m_h - w^m_d \|_0 + \frac{1}{\ell} \sum_{j=1}^{\ell} \| \nabla (w^m_{h,j} - w^m_{d,j}) \|_0 \leq
\]

\[
C \left( k^{1/2} \sum_{j=d+1}^{l} \lambda_j \right)^{1/2}, \quad m = m_i, \; i = 1, \ldots, \ell; \tag{2.19}
\]

\[
\| w^m_h - w^m_d \|_0 \leq \frac{1}{\ell} \left[ \| \nabla (w^m_h - w^m_d) \|_0 + \sum_{j=1}^{\ell-1} \| \nabla (w^m_{h,j} - w^m_{d,j}) \|_0 \right] \leq
\]

\[
C \left( k^{1/2} \sum_{j=d+1}^{l} \lambda_j \right)^{1/2} \quad + Ck, \; m \neq m_i.
\]

Combining (2.12) and (2.19) we get the following result.

**Proposition 2.4.** Under assumptions of proposition 2.3, the error estimate between the solutions of problems (2.10) and (2.18), for \( m = 1, 2, \ldots, N \), is given by:

\[
\| w^m - w^m_d \|_0 \leq C R^{s+1} + Ck + C \left( k^{1/2} \sum_{j=d+1}^{l} \lambda_j \right)^{1/2} \tag{2.20}
\]

Now, with a slight overloading of notation, we assume that the function \( f \) is given by \( f = f(y) \), where \( f \in C(\Gamma; C(0, T; L^2(D))) \) is the function employed in equation (2.6), and consider the following problem: find \( u \in H^1_0(D) \) such that \( u(x, 0) = 0 \), for all \( x \in D \), and

\[
(ut, v) + (\nabla u, \nabla v) = (f, v), \quad \forall v \in H^1_0(D). \tag{2.21}
\]

**Remark 2.2.** Note that since \( \| y - y' \| < \eta \) and under the assumption that \( f \) as a member of
$C(\Gamma;C(0,T;L^2(D)))$ is Lipschitz continuous on $\Gamma$, we get that $\|f(y) - f(y')\|_{C(0,T;L^2(D))} = \|f - g\|_{C(0,T;L^2(D))} \leq L_f \|y - y'\|$, where $L_f$ is the Lipschitz constant. Also, note that we are slightly overloading the symbol $f$ to denote both the function $f \in C(\Gamma;C(0,T;L^2(D)))$ employed in equation (2.6) and the function $f = f(y') \in C(0,T;L^2(D))$ used in equation (2.10).

Let us also consider the following problem: find $u^m_d \in X^d \subset H_h(D)$ such that $u^0_d(x) = 0$ and for $m = 1, \ldots, N$,

\[
(u^m_d, v_d) + k(\nabla u^m_d, \nabla v_d) = k(f^m, v_d) + (u^{m-1}_d, v_d), \quad \forall v_d \in X^d \subset H_h(D). \tag{2.22}
\]

Note that equations (2.22) and (2.7) are identical, according to the fact that we are using $f = f(y)$. Our aim is to find an estimate for $\|u^m - u^m_d\|_0$. First we need to prove two lemmas.

**Lemma 2.5.** Let $u$ be the solution of problem (2.21) and let $w$ be the solution of problem (2.10), then we have:

\[
\|u^m - w^m\|_0 \leq C\|f - g\|_{C(0,T;L^2(D))}. \tag{2.23}
\]

**Proof.** Let $z = u - w$ and subtract equations (2.10) and (2.21) to get:

\[
(z_t, v) + (\nabla z, \nabla v) = (f - g, v), \quad \forall v \in H^1_0(D), \tag{2.24}
\]

with $z(x, 0) = 0$, for all $x \in D$. Letting $v = z$ and integrating equation (2.24) from 0 to $t_m$, we get:

\[
\frac{1}{2} \int_0^{t_m} \frac{d}{dt}\|z\|^2 dt + \int_0^{t_m} (\nabla z, \nabla z) dt = \int_0^{t_m} (f - g, z) dt.
\]

27
This results in

\[ \frac{1}{2} \| z^m \|_0^2 \leq \int_0^T \| f - g \|_0 \| z \|_0 dt \leq \frac{1}{2} \int_0^T \| f - g \|_0^2 dt + \frac{1}{2} \int_0^T \| z \|_0^2 dt. \]

Therefore,

\[ \| z^m \|_0^2 \leq T \| f - g \|_{C(0,T;L^2(D))}^2 + \int_0^T \| z \|_0^2 dt. \]  

(2.25)

Now we need to bound \( \int_0^T \| z \|_0^2 dt \). For this, we integrate (2.24) once again but this time upto \( T \), and use the Poincaré inequality \( \| v \|_0 \leq C_p \| \nabla v \|_0 \), for each \( v \in H^1_0(D) \), to get:

\[ \frac{1}{2} \| z(T) \|_0^2 + \frac{1}{C_p^2} \int_0^T \| z \|_0^2 dt \leq \int_0^T \| f - g \|_0 \| z \|_0 dt. \]

Therefore,

\[ \int_0^T \| z \|_0^2 dt \leq C_p^2 \left( \frac{1}{2\delta} \int_0^T \| f - g \|_0^2 dt + \frac{\delta}{2} \int_0^T \| z \|_0^2 dt \right). \]

Thus,

\[ (1 - \frac{C_p^2}{2\delta}) \int_0^T \| z \|_0^2 dt \leq \frac{C_p^2}{2\delta} T \| f - g \|_{C(0,T;L^2(D))}^2. \]

Choose \( \delta > 0 \) such that \( 1 - \frac{C_p^2}{2\delta} > 0 \), and let

\[ C = \sqrt{T \left( 1 + \frac{C_p^2}{2\delta - C_p^2\delta^2} \right)}. \]

Now, equation (2.25) implies (2.23).

**Lemma 2.6.** Let \( u_d^m \) be the solution of problem (2.22) and \( w_d^m \) be the solution of problem...
(2.18), then we have:

$$\|u_d^m - w_d^m\|_0 \leq C\|f - g\|_{C(0,T;L^2(D))} \quad (2.26)$$

**Proof.** Let $z_d^m = u_d^m - w_d^m$ and subtract equations (2.18) and (2.22) to get:

$$(z_d^m, v_d) + k(\nabla z_d^m, \nabla v_d) = k(f^m - g^m, v_d) + (z_d^{m-1}, v_d), \quad (2.27)$$

$$\forall v_d \in X^d \subset H_h(D), \quad m = 1, \ldots, N,$$

with $z_d^0(x) = 0$. Let $v_d = z_d^m$ in equation (2.27) and use Poincaré inequality $\|v\|_0 \leq C_p \|
abla v\|_0$, for each $v \in H^1_0(D)$, to achieve:

$$\|z_d^m\|^2_0 + k \frac{1}{C_p^2} \|z_d^m\|^2_0 \leq k \|f^m - g^m\|_0 \|z_d^m\|_0 + \|z_d^{m-1}\|_0 \|z_d^m\|_0.$$

Therefore,

$$\left(1 + k \frac{1}{C_p^2}\right) \|z_d^m\|_0 \leq k \|f^m - g^m\|_0 + \|z_d^{m-1}\|_0,$$

which upon summation yields,

$$\|z_d^m\|_0 \leq k \|f - g\|_{C(0,T;L^2(D))} \sum_{j=1}^{m} \left(\frac{1}{1 + \frac{k}{C_p^2}}\right)^j.$$

Let $\gamma = \frac{1}{C_p^2}$ and note that $(1 + \gamma k)^m \leq e^{\gamma km}$. Moreover, setting $\zeta = 1/(1 + \gamma k)$ we find:

$$k \sum_{j=1}^{m} \left(\frac{1}{1 + \frac{k}{C_p^2}}\right)^j = k \frac{1 - \zeta^m}{\zeta - 1} = \frac{1 - \zeta^m}{\gamma} \leq \frac{1 - e^{-\gamma km}}{\gamma}.$$
Letting $C = (1 - e^{-\gamma km})/\gamma$, we get (2.26).

Now using estimates (2.20), (2.23) and (2.26) and remark 2.2, we get the following error estimate.

**Theorem 2.7.** Let $u$ be the solution of problem (2.21), and $u^m_d$ be the solution of problem (2.22), for $m = 1, \ldots, N$, we have

$$\|u^m - u^m_d\|_0 \leq C\eta + Ch^{s+1} + Ck + C\left(k^{1/2} \sum_{j=d+1}^{l} \lambda_j\right)^{1/2},$$

(2.28)

where the eigenvalues $\lambda_j$ depend on $y' \in B_\eta(y) \subset \Gamma$, and the constants $C$ depend on $y$ and $y'$, but are independent of $h, k$ and $\eta$.

### 2.3 Error analysis

In this section, we carry out an error analysis for the multi-fidelity collocation method introduced in section 2.2 for problem (2.6). In [BNT07], the authors showed that if the solution of (2.6) is analytic with respect to the random parameters, then the collocation scheme (2.9) attains an exponential error decay for $u^m_d - u^{m_p}_d$, with respect to each $p_n$.

The convergence proof in [BNT07] applies directly to our case. Therefore, our main task is to prove the analyticity property of the POD solution $u^m_d$ with respect to each random variable $y_n$. We will then only state the corresponding convergence result. In the following we impose similar restrictions on $f$ as in [BNT07, ZG12], i.e., $f$ is continuous with respect to each element $y \in \Gamma$ and that it has at most exponential growth at infinity, whenever the domain $\Gamma$ is unbounded. Moreover, we assume that joint density function $\rho$ behaves like a Gaussian kernel at infinity. In order to make it precise, we introduce the weight function

30
\( \sigma(y) = \prod_{n=1}^{r} \sigma_n(y_n) \leq 1 \), where

\[
\sigma_n(y_n) = \begin{cases} 
1 & \text{if } \Gamma_n \text{ is bounded}, \\
 e^{-\alpha_n|y_n|} & \text{for some } \alpha_n > 0 \text{ if } \Gamma_n \text{ is unbounded},
\end{cases}
\]

and the space

\[
C^0_\sigma(\Gamma; V) = \{ v : \Gamma \to V : v \text{ is continuous in } y \text{ and } \max_{y \in \Gamma} \{ \sigma(y) \| v(y) \|_V \} < +\infty \},
\]

where \( V \) is a Banach space. In what follows, we assume that \( f \in C^0_\sigma(\Gamma; C([0,T]; L^2(D))) \) and the joint probability density \( \rho \) satisfies

\[
\rho(y) \leq C_M e^{-\sum_{n=1}^{r} (\delta_n y_n)^2}, \quad \forall y \in \Gamma,
\]

for some constant \( C_M > 0 \), with \( \delta_n \) being strictly positive if \( \Gamma_n \) is unbounded and zero otherwise. Under these assumptions, the following proposition is immediate; see [BNT07].

**Proposition 2.8.** The solution of problem (2.6) satisfies \( u \in C^0_\sigma(\Gamma; C([0,T]; H^1_0(D))) \) and correspondingly, the approximate solution \( u^m_d \) resulting from (2.22) or equivalently (2.7), satisfies \( u^m_d \in C^0_\sigma(\Gamma; H_h(D)) \), for \( m = 1, \ldots, N \).

Furthermore, we have the following regularity result.

**Lemma 2.9.** The following energy estimate holds:

\[
\| u^m_d \|_{L^2(D) \otimes L^2_\rho(\Gamma)} \leq C_p^0 (1 - e^{-\frac{km}{C_p^0}}) \| f \|_{C([0,T]; L^2(D)) \otimes L^2_\rho(\Gamma)},
\]

where \( C_p \) is the Poincaré Constant.

**Proof.** Similar to the proof of Lemma 2.6. \( \square \)
2.3.1 Analyticity with respect to random parameters

We prove that the solution $u_m$ of equation (2.22) is analytic with respect to each random parameter $y_n \in \Gamma$, whenever $f(y)$ is analytic and is infinitely differentiable with respect to each component of $y$. To do this, we introduce the following notations as in [BNT07,ZG12]:

$$y_n^* = \prod_{j=1, j \neq n}^r \Gamma_j \quad \text{and} \quad \sigma_n^* = \prod_{j=1, j \neq n}^r \sigma_j.$$ 

We first make the additional assumption that for every $y = (y_n, y_n^*) \in \Gamma$, there exists $\gamma_n < +\infty$ such that

$$\left\| \partial_y f(y) \right\|_{C(0,T;L^2(D))} \leq \frac{1 + \left\| f(y) \right\|_{C(0,T;L^2(D))}}{\gamma_n^j}.$$  

(2.30)

**Remark 2.3.** Under the finite dimensional noise assumption (2.3), $f(t,x,\omega)$ is represented by a truncated linear or nonlinear expansion so that assumption (2.30) holds. For example, consider a truncated KL expansion for random forcing term $f(t,x,\omega)$ given by

$$f(t,x,\omega) = f(t,x,y(\omega)) = E[f](t,x) + \sum_{n=1}^r \sqrt{\mu_n} c_n(t,x) y_n(\omega).$$  

(2.31)

We have

$$\left\| \partial_y f(y) \right\|_{C(0,T;L^2(D))} \leq \begin{cases} \sqrt{\mu_n} \| c_n \|_{C(0,T;L^2(D))}, & j = 1, \\ 0, & j > 1. \end{cases}$$

Therefore, we can set $\gamma_n = \sqrt{\mu_n} \| c_n \|_{C(0,T;L^2(D))}$, and observe that definition (2.31) satisfies assumption (2.30). Moreover, the random forcing $f(t,x,y)$ defined in (2.31), satisfies the Lipschitz continuity assumption of remark 2.2.
Lemma 2.10. Under assumption (2.30), if the solution \( u_d^m(x, y_n, y_n^*) \) is considered as a function of \( y_n \), i.e., \( u_d^m : \Gamma_n \to C_0^0(\Gamma_n^*; L^2(D)) \), then the \( j \)-th derivative of \( u_d^m(x, y) \) with respect to \( y_n \) satisfies

\[
\| \partial_{y_n}^j u_d^m(y) \|_{L^2(D)} \leq C j! \gamma_n^j, \quad m = 1, \ldots, N,
\]  

(2.32)

where \( C \) depends on \( \| f(y) \|_{C(0,T;L^2(D))} \), and the Poincaré constant \( C_p \).

Proof. Take the \( j \)-th derivative of formulation (2.22) or equivalently (2.7) with respect to \( y_n \), and let \( v_d = \partial_{y_n}^j u_d^m(y) \) to get

\[
\| \partial_{y_n}^j u_d^m(y) \|_0^2 + k \| \partial_{y_n}^j \nabla u_d^m(y) \|_0^2 = k(\partial_{y_n}^j f^m(y), \partial_{y_n}^j u_d^m(y)) + (\partial_{y_n}^j u_d^{m-1}(y), \partial_{y_n}^j u_d^m(y)).
\]

Therefore,

\[
(1 + \frac{k}{C_p^2}) \| \partial_{y_n}^j u_d^m(y) \|_0 \leq k \| \partial_{y_n}^j f^m(y) \|_0 + \| \partial_{y_n}^{j} u_d^{m-1}(y) \|_0,
\]

which upon summation yields

\[
\| \partial_{y_n}^j u_d^m(y) \|_0 \leq k \| \partial_{y_n}^j f(y) \|_{C(0,T;L^2(D))} \sum_{i=1}^{m} \left( \frac{1}{1 + \frac{k}{C_p^2}} \right)^i.
\]

Thus,

\[
\| \partial_{y_n}^j u_d^m(y) \|_0 \leq C_p^2 (1 - e^{-\frac{km}{C_p^2}}) \frac{1}{1 + \| f(y) \|_{C(0,T;L^2(D))}} \gamma_n^j.
\]

Letting \( C = C_p^2 (1 - e^{-\frac{km}{C_p^2}}) \frac{1}{1 + \| f(y) \|_{C(0,T;L^2(D))}} \gamma_n^j \) we get (2.32).

We will immediately obtain the following theorem, whose proof closely follows the proof of Theorem 4.4 in [ZG12].
Theorem 2.11. Under assumption (2.30), the solution \( u_d^m(x, y_n, y_n^*) \) considered as a function of \( y_n \), admits an analytic extension \( u_d^m(x, z, y_n^*) \), \( z \in \mathbb{C} \), in the region of complex plane

\[
\Sigma(\Gamma_n, \tau_n) := \{ z \in \mathbb{C} : \text{dist}(z, \Gamma_n) \leq \tau_n \},
\]

where \( 0 < \tau_n < 1/\gamma_n \).

Proof. For each \( y_n \in \Gamma_n \) we define the power series \( u_d^m : \mathbb{C} \rightarrow L^2(D) \) as

\[
u_d^m(x, z, y_n^*) = \sum_{j=0}^{\infty} \frac{(z - y_n)^j}{j!} \partial_{y_n}^j u_d^m(x, y_n, y_n^*),
\]

Thus,

\[
\sigma_n(y_n) \|u_d^m(z)\|_{C^0_{\sigma_n}(\Gamma_n^*; L^2(D))} \leq \sum_{j=0}^{\infty} \frac{|z - y_n|^j}{j!} \|\partial_{y_n}^j u_d^m(y_n)\|_{C^0_{\sigma_n}(\Gamma_n^*; L^2(D))} \leq \sigma_n(y_n) C(y_n) \sum_{j=0}^{\infty} (|z - y_n| \gamma_n)^j \leq \hat{C} \sum_{j=0}^{\infty} (|z - y_n| \gamma_n)^j,
\]

where \( C(y_n) \) is a function of \( \|f(y_n)\|_{C^0_{\sigma_n}(\Gamma_n^*; C(0,T; L^2(D)))} \), and the constant \( \hat{C} \) is a function of \( \|f\|_{C^0_{\sigma_n}(\Gamma; C(0,T; L^2(D)))} \). The series is convergent for all \( z \in \mathbb{C} \), provided that \( |z - y_n| \leq \tau_n < 1/\gamma_n \). Therefore, the function \( u_d^m \) admits an analytic extension in the region \( \Sigma(\Gamma_n; \tau_n) \). \( \square \)

2.3.2 Convergence analysis

Our goal is to provide an estimate for the total error \( e^m = u^m - u^m_d, p \) in the norm \( L^2(D) \otimes L^2(\Gamma) \), for each \( m = 1, \ldots, N \). The error splits naturally into \( e^m = (u^m - u^m_d) + (u^m_d - u^m_d, p) \).

Recall that \( u^m_d, p = \mathcal{I}_p u^m_d \) and is given by (2.9). We can estimate the interpolation error \( (u^m_d - u^m_d, p) \) by repeating the same procedure as in [BNT07], using the analyticity result
of theorem 2.11. All details about the estimates of the interpolation error can be found in section 4 of [BNT07] and the references cited therein. Therefore we state the following theorem without proof.

**Theorem 2.12.** Under assumption (2.30), there exist positive constants $b_n, n = 1, \ldots, r,$ and $C$ that are independent of $h, d,$ and $p$ such that

$$
\|u_d^m - u_{d,p}^m\|_{L^2(D) \otimes L^2_\rho(\Gamma)} \leq C \sum_{n=1}^{r} \beta_n(p_n) \exp(-b_n p_n^{\theta_n}),
$$

(2.33)

where

$$
\theta_n = \beta_n = 1 \quad \text{and} \quad b_n = \log \left[ \frac{2\tau_n}{|\Gamma_n|} \left( 1 + \sqrt{1 + \frac{|\Gamma_n|^2}{4\tau_n^2}} \right) \right] \quad \text{if} \quad \Gamma_n \text{ is bounded},
$$

and

$$
\theta_n = \frac{1}{2}, \quad \beta_n = O(\sqrt{p_n}), \quad \text{and} \quad b_n = \tau_n \delta_n \quad \text{if} \quad \Gamma_n \text{ is unbounded},
$$

where $\tau_n$ is the minimum distance between $\Gamma_n$ and the nearest singularity in the complex plane, as defined in theorem 2.11, and $\delta_n$ is defined in assumption (2.29).

**Remark 2.4** (Convergence with respect to the number of collocation points). For an isotropic full tensor-product approximation, i.e., $p_1 = p_2 = \cdots = p_r = p$, the number of collocation points $\Theta$ is given by $\Theta = (1 + p)^r$. Thus, one can easily obtain the following error bound with respect to $\Theta$; see [ZG12].

$$
\|u_d^m - u_{d,p}^m\|_{L^2(D) \otimes L^2_\rho(\Gamma)} \leq \begin{cases} 
C \Theta^{-b_{\min}/r}, & \text{if} \ \Gamma \text{ is bounded,} \\
C \Theta^{-b_{\min}/2r}, & \text{if} \ \Gamma \text{ is unbounded,}
\end{cases}
$$

(2.34)

where $b_{\min} = \min\{b_1, b_2, \ldots, b_r\}$ as in theorem 2.12. The constant $C$ does not depend on $r$
Remark 2.5 (Extensions to sparse grid stochastic collocation methods). Note that the convergence as shown in (2.34) becomes slower as the dimension $r$ increases. This slowdown effect as a result of increase in dimension is called the curse of dimensionality. For large values of $r$, sparse grid stochastic collocation methods [NT09, NTW08b], specially adaptive and anisotropic ones, e.g., [MZ09, NTW08a] are more effective in dealing with this problem. Our analyticity result (theorem 2.11) combined with the analysis in [NT09, NTW08b, MZ09, NTW08a], can easily lead to the derivation of error bounds for sparse grid approximations. For instance, for an isotropic Smolyak approximation [NT09, NTW08b] with a total of $\Theta$ sparse grid points, the error can be bounded by

$$C\Theta^{-b_{\min}/(1+\log(2r))}.$$  

Here, we will give a short description of the isotropic Smolyak algorithm. More detailed information can be found in [BNR00, NTW08b]. Assume $p_1 = p_2 = \cdots = p_r = p$. For $r = 1$, let \( \{I_{1,i}\}_{i=1,2,...} \) be a sequence of interpolation operators given by equation (2.9). Define $\Delta_0 = I_{1,0} = 0$ and $\Delta_i = I_{1,i} - I_{1,i-1}$. Now for $r > 1$, let

$$\mathcal{A}(q,r) = \sum_{0 \leq i_1 + i_2 + \cdots + i_r \leq q} \Delta_{i_1} \otimes \cdots \otimes \Delta_{i_r} \quad (2.35)$$

where $q$ is a non-negative integer. $\mathcal{A}(q,r)$ is the Smolyak operator, and $q$ is known as the sparse grid level.

Now we need to find error bounds for the deterministic part of our algorithm in the $L^2(D) \otimes L^2_\rho(\Gamma)$ norm, i.e., $u^m - u^m_d$. First, note that according to (2.29), the joint density function $\rho$ behaves like a Gaussian kernel at infinity. Therefore, in practice we are literally dealing with a compact random parameter set $\Gamma$, since we can approximate $\Gamma$ with a large enough compact set. So from now on we assume that $\Gamma$ is compact. We know that $\Gamma \subset \cdots \cdots$
Thus, using the compactness assumption on \( \Gamma \), there exist \( \Upsilon \in \mathbb{N}_+ \) and \( \{i'y_i\}_{i=1}^\Upsilon \subset \Gamma \) such that \( \Gamma = \bigcup_{i=1}^\Upsilon B_{\eta}(i'y_i) \cap \Gamma \). Letting \( i'\Gamma = B_{\eta}(i'y_i) \cap \Gamma \), we can write \( \Gamma = \bigcup_{i=1}^\Upsilon i'\Gamma \).

**Theorem 2.13.** Under the Lipschitz continuity (see Remark 2.2) assumption, there exist constants \( C \) and \( \Lambda \) such that

\[
\|u_m - u_d\|_{L^2(D) \otimes L^2(\Gamma)} \leq C\eta + Ch^{s+1} + Ck + Ck^{1/4}\Lambda. \tag{2.36}
\]

**Proof.** Let us first integrate the last term in estimate (2.28). Thus, we have

\[
\int_\Gamma \left\{ C(y, y'(y)) \left( k^{1/2} \sum_{j=d(y,y'(y))+1}^{l(y,y'(y))} \lambda_j(y'(y)) \right)^{1/2} \right\}^2 \rho(y) dy =
\]

\[
k^{1/2} \int_\Gamma C(y, y'(y))^2 \lambda_j(y'(y)) \rho(y) dy =
\]

\[
k^{1/2} \sum_{i=1}^\Upsilon \left( \sum_{j=d(i'y_i)+1}^{l(i'y_i)} \lambda_j(i'y_i) \right) \int_{i'y_i} C(y, i'y_i)^2 \rho(y) dy
\]

Now letting \( \Lambda_i = \sum_{j=d(i'y_i)+1}^{l(i'y_i)} \lambda_j(i'y_i) \), and assuming \( \Lambda^2 = \max_{i=1,..,\Upsilon} \{\Lambda_i\} \), we get the following upper bound for the above expression:

\[
k^{1/2} \Lambda^2 \sum_{i=1}^\Upsilon \int_{i'y_i} C(y, i'y_i)^2 \rho(y) dy = k^{1/2} \Lambda^2 \int_\Gamma C(y, y'(y))^2 \rho(y) dy.
\]

Letting \( C^2 = \int_\Gamma C(y, y'(y))^2 \rho(y) dy \), we get the last term in (2.36). The first three terms of (2.36) can also be easily computed by integrating the first three terms of (2.28). We will
Remark 2.6. Due to the way that the POD method works, the constant \( \Lambda \) is so small that the \( k^{1/4} \) term has a very little effect on the error. The fact that the largest eigenvalues of the correlation matrix (2.15) capture most of the information is a distinct feature of ellipticity conditions. Addition of advective terms or non-linearities might affect this feature.

Combining (2.33) and (2.36), we will finally get the following total error estimate.

**Theorem 2.14.** Under assumption (2.30) and the Lipschitz continuity (see remark 2.2) assumption, there exist positive constants \( C \) and \( \Lambda \) that are independent of \( h, k, \eta \) and \( p \), and there exist constants \( b_n, n = 1, \ldots, r \), such that

\[
\| u^m - u^m_{d,p} \|_{L^2(D) \otimes L^2(\Gamma)} \leq C\eta + Ch^{s+1} + Ck + Ck^{1/4} \Lambda + C \sum_{n=1}^{r} \beta_n(p_n) \exp(-b_n\theta_n),
\]

(2.37)

where \( \theta_n, \beta_n \) and \( b_n \) are the same as the ones in theorem 2.12.

Remark 2.7. In some cases, one might be interested in estimating the expectation error, i.e., \( \| \mathbb{E}[u^m - u^m_{d,p}] \|_{L^2(D)} \). This can be easily achieved by observing that:

\[
\| \mathbb{E}[u^m - u^m_{d,p}] \|_{L^2(D)}^2 = \int_D \left( \int_{\Gamma} [u^m(x, y) - u^m_{d,p}(x, y)] \rho(y) dy \right)^2 dx
\]

\[
\leq \int_D \left( \int_{\Gamma} [u^m(x, y) - u^m_{d,p}(x, y)]^2 \rho(y) dy \int_{\Gamma} \rho(y) dy \right) dx
\]

\[
= \int_{\Gamma} \left( \int_D [u^m(x, y) - u^m_{d,p}(x, y)]^2 dx \right) \rho(y) dy
\]

\[
= \| u^m - u^m_{d,p} \|_{L^2(D) \otimes L^2(\Gamma)}.
\]

(2.38)
2.4 Numerical experiments

In this section, we provide a computational example to illustrate the advantages of multi-fidelity stochastic collocation method. Specifically, we consider problem (2.1) with $D = (0, 1)^2 \subset \mathbb{R}^2$, $T = 1$, and the forcing term being given by:

$$f(t, x, \omega) = 10 + e^{t} \sum_{n=1}^{r} y_n(\omega) \sin(n\pi x).$$

The real-valued random variables $y_n, n = 1, \ldots, r$, are supposed to be independent and have uniform distributions $U(0, 1)$. In the following, we let $r = 4$. We employ the sparse grid stochastic collocation method introduced in Remark 2.5 with sparse grid level $q = 8$. We use the Clenshaw-Curtis abscissas (see [CC60]) as collocation points. These abscissas are the extrema of Chebyshev polynomials. We divide the spatial domain $D$ into $32 \times 32$ small squares with side length $\Delta x = \Delta y = 1/32$, and then we connect the diagonals of the squares to divide each square into two triangles. These triangles constitute the triangulation $\mathcal{T}_h$, with $h = \sqrt{2}/32$. Take $k = 0.1$ as the time step increment. We use all of the time steps to form the snapshots. We employ 6 POD basis functions.

Remark 2.8. In order to form the correlation matrix (2.15) needed to find POD basis functions we are in practice using the $L_2(D)$ norm. This way we can avoid the computation of derivatives of the finite element solutions.

In the following, we compare the solution resulting from a regular isotropic sparse grid stochastic collocation method which only uses the finite element method, with the hybrid multi-fidelity method proposed in this work which employs both finite element and POD methods. In Figure 2.1, we compare the expected values resulting from the multi-fidelity method and a regular sparse grid stochastic collocation method. We take $\eta = 0.1$. Recall that for each $y \in \Gamma$ our method searches the $\eta$ neighbourhood of $y$ to check whether for some $y' \in B_\eta(y)$ problem (2.6) is already solved. If a nearby problem (at $y'$) is found to be
solved by finite element method, our algorithm uses this information to create POD basis functions and solves problem (2.6) at $y$ using Galerkin-POD method which is computationally much cheaper than finite element. Moreover, Figure 2.2 compares variances of solutions resulting from the two methods.

Figures 2.3 and 2.4, show the convergence patterns of expectations and variances of solutions with regard to $\eta$, respectively. These results validate our theoretical estimates of previous sections. We are actually comparing our multi-fidelity method with a regular sparse grid stochastic method. Note that for small enough $\eta$ (less than the shortest distance between the collocation points) we get the regular sparse grid method back. Therefore the error is zero for such a small $\eta$.

Figure 2.5 demonstrates how the number of times that the finite element code is employed increases with respect to a decrease in $\eta$. 

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2_1}
\caption{Comparison of expected values (bottom) resulting from a regular sparse grid method (top left) and the multi-fidelity method with $\eta = 0.1$ (top right).}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2_2}
\caption{Comparison of variances of solutions (bottom) resulting from a regular sparse grid method (top left) and the multi-fidelity method with $\eta = 0.1$ (top right).}
\end{figure}
Table 2.1 summarizes the results when \( \eta = 0.1 \). In this case, the number of times that the finite element code is utilized by the multi-fidelity method is 3745. Compared to 18946, the number of times that a regular sparse grid calls the finite element code.

Table 2.2 is just another way of presenting the data depicted in Figures 2.3, 2.4, and 2.5.

Remark 2.9. Note that this chapter closely follows our paper [RSa].
Chapter 3: Stochastic Burgers revisited

In this chapter we once again consider the stochastic Burgers equation (1.1). Recall that after truncating the expansion (1.2) at some point \(d\) we were able to get

\[
 u_t + \frac{1}{2} (u^2)_x = \mu u_{xx} + \sigma(x) \sum_{k=1}^{d} \xi_k h_k(t).
\]  

(3.1)

For each fixed \(\hat{\xi} = (\xi_1, \ldots, \xi_d)\), equation (3.1) can be written as,

\[
 u_t + \frac{1}{2} (u^2)_x = \mu u_{xx} + f_d(t, x),
\]  

(3.2)

where \(f_d(t, x) = \sigma(x) \sum_{k=1}^{d} \xi_k h_k(t)\). Recall that we needed to solve the deterministic equation (3.2) many times for different values of \(\hat{\xi}\). In the following, we revisit the low fidelity algorithm of Group POD and apply it on

\[
 u_t + \frac{1}{2} (u^2)_x = \mu u_{xx} + g_d(t, x),
\]  

(3.3)

where \(g_d(t, x) = \sigma(x) \sum_{k=1}^{d} \zeta_k h_k(t)\), which is practically equation (3.2) evaluated at the new parameter \(\hat{\zeta} = (\zeta_1, \ldots, \zeta_d)\). Note that \(\hat{\xi}\) and \(\hat{\zeta}\) are not necessarily equal. Consequently, \(f_d\) and \(g_d\) are generally different. We solve equation (3.2) using the GFE method (1.6).
3.1 Group POD as a low-fidelity deterministic algorithm

Solution to equations (1.6), with $V(t) = [(f_d(t, \cdot), \beta_i)]_{i=1}^N$, gives an approximate solution to (3.2) given by $w(t, x) = \sum_{j=1}^{N} \alpha_j(t) \beta_j(x)$. Let $\{w(t_i, \cdot), i = 1, \ldots, S\}$ be a set of $S$ “snapshots”, where $t_1 < t_2 < \ldots < t_S$ are equally spaced points of time in the interval $[0, T]$. Furthermore, define $Y = [\alpha(t_1) \cdots \alpha(t_S)]$ to be the snapshots matrix. Let $L$ be a lower triangular matrix resulting from the Cholesky decomposition of the mass matrix $M$, i.e., $M = LL^T$. Define $\tilde{Y} := L^T Y$ to be the weighted snapshots matrix. The correlation matrix $K$ of the data set $\{w(t_i, \cdot), i = 1, \ldots, S\}$ is given by

$$K := \left(1_S \frac{1}{S} (w_i, w_j)\right)_{i,j=1}^S = \frac{1}{S} Y^T M Y = \frac{1}{S} \tilde{Y}^T \tilde{Y}$$

where $w_i = w(t_i, \cdot), i = 1, \ldots, S$. Let $\{\lambda_k, Z_k\}$ denote the eigenvalues and the corresponding normalized eigenvectors of $K$. Define $Z$ to be the matrix $[Z_1 | \ldots | Z_S]$. The POD basis functions $\{\psi_k\}_{k=1}^S$ are given as

$$\psi_k = \frac{1}{\sqrt{S \lambda_k}} \sum_{i=1}^{S} [Z]_{i,k} w_i, \quad k = 1, \ldots, S. \tag{3.5}$$

Note that

$$\frac{1}{S} \tilde{Y}^T \tilde{Y} Z = Z \Lambda, \tag{3.6}$$

where $\Lambda := diag(\lambda_k, k = 1, \ldots, S)$. Let us express the POD basis function $\psi_j$ as $\psi_j(x) = \sum_{i=1}^{N} \psi_{i,j} \beta_i(x)$ and let $\psi = (\psi_{i,j})$ for $i = 1, \ldots, N$ and $j = 1, \ldots, S$. Using (3.5) we get

$$\psi = Y Z (S \Lambda)^{-\frac{1}{2}}. \tag{3.7}$$
Using exactly the same procedure as the one in Group POD introduced in section 1.3, with $f_d$ being replaced by $g_d$, we can get an approximate solution $u_d(t, x)$ to (3.3).

### 3.2 Local improvements to POD basis functions

Note that we want to use the POD basis functions found at $\hat{\xi}$ to solve the deterministic problem (3.3) at a nearby point $\hat{\zeta}$. It is a well known fact that if $\hat{\zeta} = \hat{\xi}$ we get sufficiently accurate approximations of the solution of problem (3.3) or equivalently (3.2). However, for $\hat{\zeta} \neq \hat{\xi}$, we usually experience a drop in accuracy. In order to deal with issue, we use the sensitivity analysis of POD basis functions to improve the accuracy of the solution found at $\hat{\zeta}$. Note that the POD bases (3.5) are a function of $\hat{\xi}$. We are specifically interested in the sensitivity of these POD bases in the direction of $\hat{\zeta} - \hat{\xi}$. To do so, we introduce a new parameter $\theta \in [0, 1]$ and consider the mapping $\hat{\xi} + \theta(\hat{\zeta} - \hat{\xi})$. Therefore, the POD bases can be considered to be a function of $\theta$. We start by noting that:

$$K Z_k = \lambda_k Z_k, \quad (3.8)$$

where $K$ is defined by (3.4), and $\{\lambda_k, Z_k\}$ denote the eigenvalues and the corresponding normalized eigenvectors of $K$. We assume that the entries of $K$, $Z$, and $\Lambda$ are smooth functions of the parameter $\theta$ so that (3.8) can be differentiated with respect to $\theta$. In what follows, partial derivative of any matrix or vector is denoted using the superscript $(\theta)$.

Therefore, by implicit differentiation of (3.8) with respect to $\theta$ we get:

$$(K - \lambda_k I) Z_k(\theta) = -(K(\theta) - \lambda_k(\theta) I) Z_k. \quad (3.9)$$

Equation (3.9) has a solution only if the right-hand side vector belongs to the range of $K - \lambda_k I$ and thus must be orthogonal to $ker(K - \lambda_k I)$ which is spanned by $Z_k$. Therefore,
we should have that
\[ Z_k^T (K^{(\theta)} - \lambda_k^{(\theta)} I) Z_k = 0. \]  
(3.10)

Since \( Z_k \) has unit norm, the sensitivity of the eigenvalues is obtained by (see e.g. [Lan64, FKS+68, MH88, SLO94])
\[ \lambda_k^{(\theta)} = Z_k^T K^{(\theta)} Z_k. \]  
(3.11)

Note that \( K = \frac{1}{S} \hat{Y}^T \hat{Y} \) and \( \hat{Y} = L^T Y \). Therefore, \( K^{(\theta)} = \frac{1}{S} (\hat{Y}^{(\theta)^T} \hat{Y} + \hat{Y}^T \hat{Y}^{(\theta)}) \) and \( \hat{Y}^{(\theta)} = L^T Y^{(\theta)} \). Provided that we know what \( Y^{(\theta)} \) is, we can now fully characterize the solution \( Z_k^{(\theta)} \) of equation (3.9). We find a particular solution \( S_k \) of (3.9) in the least-square sense (obtaining the minimum norm solution). Since \( \lambda_k \) is simple, for all \( \varrho \in \mathbb{R} \), \( S_k + \varrho Z_k \) is the general expression for the solutions of (3.9). To determine the particular solution of (3.9) which corresponds to the sensitivity \( Z_k^{(\theta)} \) of \( Z_k \), we need an additional condition. This comes naturally from the normalization condition \( Z_k^T Z_k = 1 \) which was employed to specify \( Z_k \). Differentiating the normalization condition we get \( Z_k^T Z_k^{(\theta)} = 0 \) and consequently \( \varrho = -Z_k^T S_k \). Finally,
\[ Z_k^{(\theta)} = S_k - (Z_k^T S_k) Z_k. \]  
(3.12)

Once the sensitivity of matrices \( Z \) and \( \Lambda \) are determined, the sensitivity of POD basis modes \( \psi \) and POD bases \( \psi_k \) are straightforward to be computed by differentiating (3.7). More specifically,
\[ \psi^{(\theta)} = Y^{(\theta)} Z (S \Lambda)^{-1/2} + Y Z^{(\theta)} (S \Lambda)^{-1/2} + Y Z S^{-1/2} (\Lambda^{-1/2})^{(\theta)} \]
\[ = Y^{(\theta)} Z (S \Lambda)^{-1/2} + Y Z^{(\theta)} (S \Lambda)^{-1/2} - \frac{1}{2} Y Z S^{-1/2} (\Lambda^{-1/2} \Lambda^{(\theta)} \Lambda^{-1}) \]
\[ = Y^{(\theta)} Z (S \Lambda)^{-1/2} + Y Z^{(\theta)} (S \Lambda)^{-1/2} - \frac{1}{2} \psi \Lambda^{(\theta)} \Lambda^{-1}. \]  
(3.13)
To complete the sensitivity analysis of the POD bases, we still need to find the sensitivity of the snapshot data matrix $Y^{(\theta)}$. This can be done by the sensitivity analysis of equation (3.2).

### 3.2.1 Sensitivity analysis of the Burgers equation

Let $u$ be the solution of equation (3.2) and let $z = \partial_\theta u$ be the partial derivative of $u$ with respect the parameter $\theta$. Taking the derivative of equation (3.2) with respect to $\theta$, we get that $z$ should satisfy

$$z_t + (zu)_x = \mu z_{xx} + \partial_\theta f_d(t, x),$$

where $\partial_\theta f_d(t, x) = \partial_\theta [\sigma(x) \sum_{k=1}^{d} (\xi_k + \theta(\zeta_k - \xi_k))h_k(t)] = \sigma(x) \sum_{k=1}^{d} (\zeta_k - \xi_k)h_k(t)$, with zero boundary and initial conditions. Note that equation (3.14) is no longer non-linear and can be efficiently solved using a regular Finite Element method in a negligible amount of time. The finite element basis functions are assumed to be as before and we are seeking the solution in the space $W_N([0,1]) = \text{span}\{\beta_j, j = 1, \ldots, N\}$ defined earlier. Let $z(t, x) = \sum_{i=1}^{N} z_i(t) \beta_i(x)$ be the solution resulting from solving (3.14) with the Finite Element method. Then the sensitivity of the snapshot matrix $Y$ is given by $Y^{(\theta)} = (z_i(t_j)), i = 1, \ldots, N$ and $j = 1, \ldots, S$. This completes the sensitivity analysis of POD basis functions in the directions of $\hat{\zeta} - \hat{\xi}$.

### 3.2.2 Improving POD bases

Following [HBP09], we state two ideas for constructing improved reduced bases.

1. **Extrapolated basis**: Note that POD bases introduce in (3.5) are functions of $\hat{\xi}$ and consequently functions of $\theta$ used in the transformation $\hat{\xi} + \theta(\hat{\zeta} - \hat{\xi})$. Let us use $\psi_k(\theta)$ to emphasize this dependence. Note that when $\theta = 0$ we are considering the POD
basis functions at $\hat{\xi}$ and when $\theta = 1$ we are considering them at $\hat{\zeta}$. Now let us use

$$\psi_k(\theta) \simeq \psi_k(0) + \Delta \theta \frac{\partial \psi_k}{\partial \theta}(0)$$ (3.15)

to approximate $\psi_k(\theta)$. The capability of this extrapolation obviously depends on the assumption that POD modes behave nearly linear with respect to the parameter $\theta$. However, using this method, the dimension of the reduced basis is preserved. Other approaches based on this idea can be found in [LLN05, LFL06, MSN07]. These papers motivate the extrapolation approach based on mode sensitivity, by showing an increase in robustness of the derived POD models with respect to parameter change.

2. **Expanded basis:** The sensitivity of the modes generally seem to span a different subspace than the POD modes. Therefore, it seems plausible to expect that if we seek the approximate solution in the space spanned by the union of these two sets, we can represent a broader range of solutions. Therefore, we use $\{\partial_\theta \psi_k\}$ to expand the original POD basis functions $\{\psi_k\}$. By a misuse of notation, we are still using $W_{N,M}(\{[0,1]\}) = \text{span}_{k=1,...,M}\{\psi_k, \partial_\theta \psi_k\}$ to denote the space where we seek the solution of equation (1.11). The underlying assumption of this approach is that $W_{N,M}(\{[0,1]\})$ is well suited to address the change in the solution induced by a change in parameter. This indeed is a legitimate assumption since the sensitivities represent changes in the parameter space. However, the dimension of the reduced basis is now doubled.

### 3.3 Multi-fidelity Stochastic Collocation

We are finally in a position to demonstrate the multi-fidelity stochastic collocation method. Our aim to approximate the solution of (3.1) in the space $V_{N,p} = L_2([0,T]; W_N([0,1])) \otimes$
\( \mathcal{P}_p(\mathbb{R}^d) \), where \( W_N([0,1]) = \text{span}\{\beta_j\} \) is the finite element space, and \( \mathcal{P}_p(\mathbb{R}^d) \) is the span of tensor product polynomials with degree at most \( p = (p_1, \ldots, p_d) \). Choose \( \eta > 0 \) to be a small real number. The procedure for approximating the solution of (3.1) is divided into two parts:

1. Fix \( \hat{\zeta} \in \mathbb{R}^d \), and search the \( \eta \)-neighbourhood \( B_\eta(\hat{\zeta}) \) of \( \hat{\zeta} \). We use \( B_\eta(\hat{\zeta}) = \{ \hat{\xi} \in \mathbb{R}^d : |\xi_k - \zeta_k| < \eta, \forall k = 1, \ldots, d \} \). If problem (3.2) is not already solved by the GFE method for any nearby problem with \( \hat{\xi} \in B_\eta(\hat{\zeta}) \), let \( \hat{\xi} = \hat{\zeta} \) and solve problem (3.2) using the GFE method. In contrast, if equation (3.2) is already solved for some points in \( B_\eta(\hat{\zeta}) \), pick the closest one to \( \hat{\xi} \) and call it \( \hat{\xi} \). In either case, use the solution at \( \hat{\xi} \in B_\eta(\hat{\zeta}) \) to find a small number of suitable basis functions resulting from local improvements to POD bases using sensitivity analysis. Let \( W_{N,M}([0,1]) \subset W_N([0,1]) \) be the span of these basis functions. Now use the Group POD method to solve problem (3.3) at \( \hat{\zeta} \in \mathbb{R}^d \) and get the solution \( u_d(\hat{\zeta}, t, x) \).

2. Collocate on zeros of suitable orthogonal polynomials and build the interpolated solution \( u_{d,p} \in V_{N,p} \) using

\[
 u_{d,p}(\hat{\zeta}, t, x) = \mathcal{I}_p u_d(\hat{\zeta}, t, x) = \sum_{j_1=1}^{p_1+1} \cdots \sum_{j_d=1}^{p_d+1} u_d(\zeta_1, \ldots, \zeta_d, t, x)(l_{j_1}(\hat{\zeta}) \otimes \cdots \otimes l_{j_d}(\hat{\zeta}) ,
\]

where the functions \( \{l_{jk}\}_{k=1}^{d} \) can be taken as Lagrange polynomials. Using this formula, as described in [BNT07], mean value and variance of \( u_d \) can also be easily approximated.
3.3.1 Generalization to Sparse Grids

Here, we give a short description of the isotropic Smolyak algorithm. More detailed information can be found in [BNR00, NTW08b]. Assume \( p_1 = p_2 = \cdots = p_d = p \). For \( d = 1 \), let \( \{I_{1,i}\}_{i=1,2,...} \) be a sequence of interpolation operators given by equation (3.16). Define \( \Delta_0 = I_{1,0} = 0 \) and \( \Delta_i = I_{1,i} - I_{1,i-1} \). Now for \( d > 1 \), let

\[
\mathcal{A}(q,d) = \sum_{0 \leq i_1 + i_2 + \cdots + i_d \leq q} \Delta_{i_1} \otimes \cdots \otimes \Delta_{i_d}
\]  

where \( q \) is a non-negative integer. \( \mathcal{A}(q,d) \) is the Smolyak operator, and \( q \) is known as the sparse grid level. Now instead of (3.16), \( \mathcal{A}(q,d)u_d(\hat{\xi},t,x) \) can be used to approximate the solution \( u_d \) of (3.1). This way one reduces the number of grid points on which the deterministic algorithms should be employed.

3.4 Numerical experiments

In this section, we consider equation (3.1) given once again below for conveniences.

\[
u_t + \frac{1}{2}(u^2)_x = \mu u_{xx} + \sigma(x) \sum_{k=1}^{d} \xi_k h_k(t),
\]

\((t,x) \in (0,T] \times [0,1], u(0,x) = u_0(x), u(t,0) = u(t,1) = 0,\) where \( u_0 \in L_2([0,1]) \) is a deterministic initial condition. In the following numerical experiments, before employing the full-blown version of the multi-fidelity algorithm, we first consider the case when we are still utilizing a single point \( \xi = 0 \) (similar to Chapter 1) in the stochastic parameter domain to generate the POD bases, however, this time we are performing local improvements using the extrapolated basis technique. We let \( T = 1.0, u_0(x) = (e^{\cos(5\pi x)} - \frac{3}{2}) \sin(\pi x), \sigma(x) = 0.01 \) and \( \mu = 1/200.0 \). In Figure 3.1 we observe that the mere usage of improved basis functions without any increase in the number of times that the high fidelity algorithm is employed
fixes the issue brought up in Figure 1.2. Table 3.1 compares the corresponding errors of the two methods with the Monte Carlo method being the point of reference.

![Comparison of Methods](image)

For the rest of this section, unless otherwise stated, we assume that $\sigma(x) = 0.1 \cos(4\pi x)$ and $\mu = 1/100$. We let $T = 0.8$ and $u_0(x) = (e^{\cos(5\pi x)} - \frac{3}{2}) \sin(\pi x)$. We are still projecting the Brownian motion in $[0,T]$ on the trigonometric basis functions $h_k(t)$ in $L_2([0,T])$ given by

$$h_1(t) = \frac{1}{\sqrt{T}}, \quad h_k(t) = \sqrt{\frac{2}{T}} \cos \left( \frac{(k-1)\pi t}{T} \right), \quad k \in \{2,3,\ldots\}.$$ (3.19)
Let us first study the effect of local improvements to POD basis functions. Choose \( \hat{\xi} \) and \( \hat{\zeta} \) to be two \( d \) dimensional vectors with Gaussian distributed randomly chosen entries. We again consider the transformation \( \hat{\xi} + \theta(\hat{\zeta} - \hat{\xi})/||\hat{\zeta} - \hat{\xi}|| \). We let \( \theta \) to change in the interval \([-1/2, 1/2]\). We compute the POD basis functions at \( \hat{\xi} \) and use them, along with their extrapolated and expanded local improvements, to solve the nearby problem at \( \hat{\xi} + \theta(\hat{\zeta} - \hat{\xi})/||\hat{\zeta} - \hat{\xi}|| \) using the Group POD method. We then compare the results with the ones from the GFE method. For the finite element code we partition the spatial domain \([0, 1]\) into 64 intervals. We also divide the time domain \([0, T]\) into 200 time steps. For the reduced order models, we use 10 POD basis functions which results in 10 extrapolated basis functions and 10+10 extended basis functions. We also consider the case when 20 POD basis functions and consequently 20 extrapolated bases are employed, for comparison. We let \( d = 10 \). Figure 3.2 shows the typical behaviour of Group POD method when

![Figure 3.2: Comparison of the effects of extrapolated and expanded local improvements to POD basis functions](image)
POD, Extrapolated, and Expanded basis functions are employed. The authors believe that the improvement in accuracy that is achieved by employing Expanded basis functions is not worth the increase in the number of bases. Therefore, in the multi-fidelity collocation method proposed earlier we use Extrapolated basis functions to locally improve the performance of Group POD method. Now we apply the multi-fidelity collocation method. Let us assume that $\eta = 1/2$ and $d = 3$. For the finite element code we partition the spatial domain $[0, 1]$ into 32 intervals. We also divide the time domain $[0, T]$ into 20 time steps. We use 10 extrapolated POD basis functions. We employ the Smolyak algorithm with sparse grid level $q = 8$. We use the Clenshaw-Curtis abscissas (see [CC60]) as collocation points. These abscissas are the extrema of Chebyshev polynomials. In Figure 3.3 we compare expectations and second moments of solutions resulting from our multi-fidelity method (GFE & Group POD) and the ones resulting from a regular sparse grid method with the full employment of GFE as the high fidelity algorithm. In this figure, we are also including the solutions coming out of the Monte-Carlo method with the full employment of the high fidelity algorithm for reference.

For this value of $\eta = 1/2$, the number of times that our algorithm calls the high fidelity (GFE) code is reduced to 2030. Compare it to 6018, the number of times that the GFE code is called when sparse grid stochastic collocation with full employment of the high-fidelity algorithm is utilized. Comparing the two methods, assuming that sparse grid stochastic collocation with full employment of the high-fidelity algorithm is accurate enough, we get that the error in expectation is given by $8.2 \times 10^{-4}$ and the one in the second moment is $1.4 \times 10^{-3}$.

Figure 3.4, shows the convergence patterns of expectations and second moments of solutions with regard to $\eta$. We are in fact comparing our multi-fidelity method with a regular sparse grid stochastic collocation method. Note that for small enough $\eta$ (less than the shortest distance between the collocation points) we get the regular sparse grid method back. Therefore the error is zero for such a small $\eta$. 

53
Figure 3.3: Expectation and Second Moment of the solution given at the final time $T = 0.8$ when $d = 3$, for sparse grid level 8 and $\eta = 0.5$. 
Figure 3.4: $L_2([0,1])$-norm convergence pattern of Expectation and Second Moment of the solution given at the final time $T = 0.8$ when $d = 3$, for sparse grid level 8.
Figure 3.5 demonstrates how the number of times that the finite element code is employed increases with respect to a decrease in $\eta$. Table 3.2 is just another way of presenting the data depicted in Figures 3.4 and 3.5.

**Remark 3.1.** *Note that this chapter closely follows our paper [RSb].*

Conclusions

In this work, we have proposed a method to enhance the performance of stochastic collocation methods using proper orthogonal decomposition. We have carried out detailed error analyses of the proposed multi-fidelity stochastic collocation methods for parabolic partial differential equations with random forcing terms. We illustrated and supported our theoretical analyses with a numerical example. The analysis of this work can simply be generalized to parabolic partial differential equations with random initial conditions and random coefficients. Our method only requires a well-posedness argument of the corresponding deterministic equations. We have also chosen to apply our method to the stochastic Burgers equation because of its tractability and because lots of powerful model reduction techniques such as group POD existed for this equation. Our method enhances the power of stochastic collocation methods in handling more stochastic differential equations. Our work provides another reason for the importance of research in Model reduction techniques. We believe that more research can follow our work and apply our method to more interesting problems. Such problems can be in fluid dynamics and fluid structure interactions. Navier-Stokes equations under uncertainty can for instance be a reasonable next step.
