## DEDICATION

This is dedicated to my loving family, who has given me unwavering trust, support and patience. Thank you for believing in me, always.

## ACKNOWLEDGEMENTS

I would like to thank Stephanie Coon who collaborated on cell line DNA preparation and sequence analysis, Masoomah Sikaroodi, who performed automated sequencing, Amy J VanMeter for the work on the protein arrays, Manpreet Rhandawa. for her help with the FACS analysis and all of my colleagues who have gracefully shared their time and experience.

I would like to thank my committee members for their contributions, and Dr. Baranova, my dissertation adviser, who always goes above and beyond the call of duty in sharing her time and experience with me and the rest of her students. And last but certainly not least, I would like to thank my family for their boundless support and encouragement.

## LIST OF ABBREVIATIONS

7-AAD – 7-amino-actinomycin  
ATCC – American Type Culture Collection  
B-CLL – B-cell Chronic Lymphocyte Leukemia  
BMSCs – Bone marrow stromal cells  
BTB/POZ – BTB, for BR-C, ttk and bab, and the POZ also known as poxvirus and zinc finger  
CLL – Chronic Lymphocyte Leukemia  
COOL – Proteins homologous to C-end of KCNRG isoform S  
DAPI – 4',6-diamidino-2-phenylindole  
DiOC18 – 3-di-octadecyloxacarbocyanine perchlorate  
DLBL – Diffuse Large B-cell Lymphomas  
DLEU1 – BCMS (B-Cell Multiple Splicing)  
DLEU2 – BCMSUN (BCMS-Upstream Neighbor) gene  
ECM – Extracellular Matrix  
ELISA – Enzyme-Linked ImmunoSorbent Assay  
ELM – Eukaryotic Linear Motif Resource  
ER – Endoplasmic reticulum  
ERAD – ER-associated degradation pathway  
EST – Express sequence tags  
EthD-1 – Ethidium Homodimer  
EV – Empty Vector  
FACS – Fluorescence-activated cell sorting  
FDR – False Discovery Rate  
FISH – Fluorescent in situ Hybridization  
FL – Follicular Lymphomas  
FSC – Forward Scatter  
GIST – Gastrointestinal Stromal Tumors  
GWA – Genome Wide Association  
HCC – Hepatocellular Carcinoma  
HL – Hodgkin Lymphomas  
HL-60 – Human Promyelocytic Leukemia  
ICRF – Imperial Cancer Research Foundation, United Kingdom  
INR – Core Promoter Initiator Element  
KCNRG V1 – KCNRG variant 1, corresponding to protein product KCNRG - S  
KCNRG V2 – KCNRG variant 2, corresponding to protein product KCNRG - L  
Kir – two trans-membrane helix inward rectifier channel class  
Kv – six trans-membrane helix voltage gated potassium channel class  
LANL – Los Alamos National Laboratory, United States

LNCaP – Androgen-sensitive human prostate adenocarcinoma derived from lymph node metastasis  
 LOH – The loss of heterozygosity  
 MB – Medulloblastoma  
 MCL – Mantle Cell Lymphoma  
 MCL – Mantle Cell Lymphomas  
 MDR – Minimally Deleted Regions  
 MM – Multiple Myeloma  
 MZBL – Marginal Zone B-cell Lymphomas  
 NCBI – National Center for Biotechnology Information  
 NZB – New Zealand black mouse  
 NZW – New Zealand white mouse  
 ORF – Open reading frame  
 PAH – Pulmonary Arterial Hypertension  
 PBL – Peripheral Blood Lymphocytes  
 PBS – Phosphate buffered saline  
 PI – Propidium iodide  
 PME – Progressive myoclonic epilepsy  
 RAMS – Russian Academy for Medical Science  
 RB1 – Retinoblastoma gene 1  
 RBCC/TRIM – zinc-binding RING domains, a B-box, and a coiled-coil domain  
 RCMG – Russian Center for Medical Genetics, Moscow, Russia  
 RFP2 – Ret Finger Protein 2  
 RPA – Reverse Phase-protein Array  
 RPMI-8226 – Multiple Myeloma cell line with lymphoblast-like appearance  
 RT-PCR – Real time Polymerase Chain Reaction  
 SAM – Significance Analysis of Microarrays  
 SLL – Small Lymphocytic Lymphomas  
 SNPs – Single Nucleotide Polymorphisms  
 SSC – Side Scatter  
 SSCP – Single-strand conformational polymorphism  
 SSDSPA – Class IV WW domain interaction motif involved in phosphorylation-dependent interaction  
 STK2 – serine-threonine kinase  
 STS – Sequence tagged site  
 T1 – Tetramerization Domain  
 T2D – Type 2 diabetes  
 TL – T-cell Lymphomas  
 T-PLL – T-cell Prolymphocytic Leukemia  
 TSG – Tumor suppressor gene  
 VDAC – Mitochondrial Voltage-Dependent Anion Channels  
 YAC – Yeast Artificial Chromosome

## ABSTRACT

### ROLE OF KCNRG IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

Aybike Birerdinc, PhD

George Mason University, 2008

Dissertation Director: Ancha Baranova

B-cell chronic lymphocyte leukemia (B-CLL) accounts for approximately 30% of all leukemias in the Western world and has so far been treated with variable success. The newly characterized *KCNRG* gene has been mapped to chromosome 13q14.3. *KCNRG* is thought to be a tumor suppressor gene involved in the development of B-cell chronic lymphocytic leukemia due to its significant homology to the tetramerization (T1) domain of the voltage-gated potassium channels (Kv channels) and an ability to suppress growth-stimulating Kv currents. Since point mutations of *KCNRG* have not been found in B-CLL samples, a novel approach for its study based on a haploinsufficiency model was suggested. The aim of this study is to determine whether the *KCNRG* gene functions as growth suppressor in tumor cell lines and to elucidate a putative role for the loss of this gene in the development and the progression of B-CLL. Overexpression studies of *KCNRG* were performed in an attempted to determine the involvement of *KCNRG* in

apoptosis, differentiation, and invasion of cultured human tumor cells, and the effects of overexpression of *KCNRG* on gene expression and proteomics profiles were quantified.

## **CHAPTER 1: Background and Significance**

B-cell Chronic Lymphocytic Leukemia (B-CLL) is one of the most commonly diagnosed leukemias in the Western world (Byrd et al. 2004). This disease accounts for ~30% of all human leukemias and is most commonly seen amongst the elderly; about two-thirds of the patients are older the age of 60 (Zwiebel et al. 1998). The clinical course of CLL is subdivided into five stages: during stage O, only bone marrow and blood lymphocytosis is seen; during stage I, it is possible to detect lymphocytosis with enlarged nodes; at stage II, lymphocytosis with enlarged spleen and/or liver involvement can be detected; at stage III, lymphocytosis with anemia is observed; and at stage IV lymphocytosis with thrombocytopenia can be seen (Rai KR et al. 1975, Binet at al. 1981). As can be observed from the clinical staging CLL develops progressively.

On a cellular level the disease progresses due to the prolonged survival of B-CLL cells arrested in the G0 stage of the cell cycle (Gale et al. 1987). This prolonged survival causes the accumulation of slowly proliferating CD5(+) B lymphocytes in the blood, bone marrow, and lymphatic tissues leading to the clinical manifestations of the disease. These quiescent small lymphocytes, CD5(+) B lymphocytes are frozen at an early step of maturation and have decreased susceptibility to apoptotic cell death. Latter features are commonly attributed to the imbalance in various cytoplasmic pro-survival and pro-death pathways, including the BCR-signaling pathway (Danilov AV et al. 2006; Ougolkov

2007, Iglesias-Serret 2007). In addition, a small number of "atypical", Ki-67 expressing lymphocytes are frequently observed in the bone marrow of CLL patients (Bueso-Ramos CE. et al. 2004). Proliferation rates of these lymphocytes vary among patients and even among subpopulations of cells within the leukemic clones of individual patients (Chiorazzi N, Ferrarini M 2006). A newly evolving point of view stresses that blood lymphocyte count in B-CLL patients represents a dynamic interplay between ongoing birth and death within the clones rather than a linear, monotonous accumulation of inert leukemic cells (Chiorazzi N, Ferrarini M 2006).

Historically CLL has been treated with mixed success. More often than not, classical chemotherapy methods are only marginally effective and rarely yield complete responses. Typically the survival times are ~5-8 years although this is highly variable (Dighiero et al. 1998; Montserrat E. 2004). Therefore, understanding the genetic pathways involved in B-CLL is necessary to design more effective therapeutic approaches.

### **Genetic aberrations seen in CLL**

From a genetic perspective, an abnormal karyotype, as detected by fluorescent in situ hybridization (FISH), can be observed in the tumor cells of the majority (90%) of patients with CLL cases (Döhner et al. 1999). The most common chromosomal abnormalities are deletions of the chromosomal band 13q14 which occur in ~50-70% of all cases of CLL (Liu Y et al. 1997). The next most common deletions are found in 11q22-q23 region accounting for ~19% and are usually associated with extensive lymph

node involvement and an aggressive form of the disease (Cuneo A. et al. 2002; Dohner H. et al. 2000). The deletions in 11q22-q23 region may not be a primary event, and may actually arise as a secondary event in cases where there is already an aberration in 13q14 (Cuneo A. et al. 2002).

Other aberrations include trisomy 12, which is considered to be atypical CLL and is usually associated with poor prognosis. Trisomy 12 in CLL coincides with the expression of the CD11a marker (O'Connor S.J. et al. 2000). In 1999 Caligaris-Cappio et al. showed that trisomy 12 is associated with the un-mutated status of the immunoglobulin variable heavy chain (VH) genes, and corresponds to atypical cellular morphology (Caligaris-Cappio et al. 1999). Another type of aberration, one that involves deletions in the 17p13 region, seems to be more common in the late stage of the disease and is believed to involve the TP53 tumor suppressor gene. This type of deletion is also associated with shortened survival (Shaw GR and Kronberger DL 2000 and Haslinger et al. 2004). Finally, the deletions in 6q21 are found to occur in 7% of B-CLL cases. Deletions of 6q21 are associated with larger tumor size (lymphadenopathy), however, no correlation with negative prognosis has been evident (Stilgenbauer et al. 1999).

Using FISH, deletions in 13q14.3 are detected in > 95% of the clonal population of malignant cells, hence giving rise to the belief that deletions in 13q14.3 may be an early or even initiating event in CLL. In contrast, other chromosomal abnormalities are less prevalent, being present in only a small proportion of the CLL cohort (Jabbar SA et al. 1995).

### **Fine mapping of 13q14.3 region deleted in CLL**

The search for a TSG involved in B-CLL was stimulated by the fact that the retinoblastoma gene (RB1), a well-known TSG residing in 13q14.3, remains functional in some B-CLL patients, while a region adjacent to RB1 on the telomere side is often deleted (L.A. Hawthorn et al. 1993, Y. Liu et al. 1992). This region was assumed to contain a TSG critical for B-CLL development. At the time, the 13q14.3 region, as well as most of the human genome landscape, was uncharted territory: markers suitable for physical mapping were several mega-bases apart from each other, which hindered precise localization of the chromosomal breakpoints in CLL cells.

Through concerted efforts by a number of research teams, several STS-markers were mapped to the region of interest and used as anchors for yeast artificial chromosome (YAC) contigs (V.M. Brodyanskii et al. 1995). These markers were also used as probes for Southern blotting of DNA of patients in order to pinpoint the area deleted in B-CLL cases (Y. Liu et al. 1995; M.M. Corcoran et al. 1991). Fine structural analysis of the 13q14 region of the human genome was a necessary step in initial attempts to clone CLL TSG. Those attempts were supported in the frame of Chromosome 13 Mapping and Sequencing Project of the Human Genome Program. First, a contig overlapping the 13q14.3 region was built using cosmid libraries constructed by the Los Alamos National Laboratory (LANL, United States) and the Imperial Cancer Research Foundation (ICRF, United Kingdom). About 30,000 individual cosmids (equivalent to approximately nine spans of chromosome 13) individually stored in 96-well plates were used as probes for cross hybridization, revealing overlapping cloned DNA fragments covering more than

600 kb of the chromosome 13 region frequently deleted in B-CLL (B.I. Kapanadze et al. 1997). Further delineation of the region was achieved by analysis of the loss of heterozygosity (LOH) patterns and fluorescence in situ hybridization (FISH) studies. As a result, the minimal region lost in B-CLL was reduced to 300 kb (M.M Corcoran et al. 1991; M.C. Devilder et al. 1995).

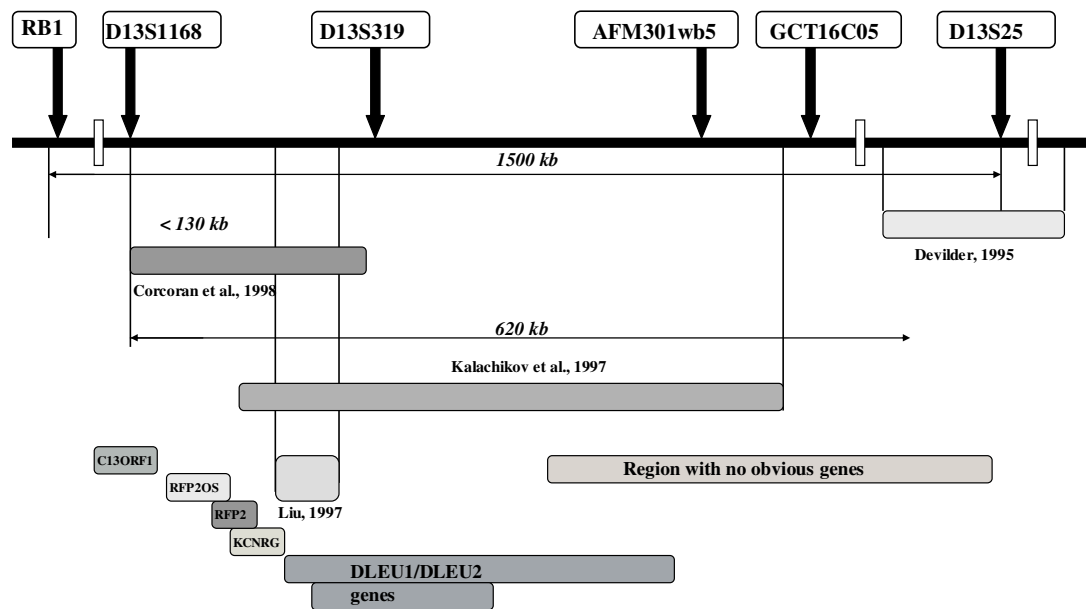

Fig.1. Map of regions identified as having deletions by various independent researchers.

The minimally deleted region was localized between two STSs, D13S1149 and D13S25 (Fig. 1); another marker, D13S319, proved to be the one most often eliminated by deletion. Further minimization attempts were performed in different labs which examined independent groups of B-CLL patients. Surprisingly, each group succeeded in chopping the minimally deleted region down to less than 300 kb, but the resulting regions

were minimally overlapping, and in extreme cases, deleted regions were mapped 200 kb apart (M.C. Devilder et al. 1995; I. Bouyge-Moreau et al. 1997). Since further minimization of the deleted region yielded discrepant results, a physical map with a higher resolution was necessary. Southern hybridization of DNA probes representing 300bp-2 kb fragments of cosmid clones with genomic DNA of B-CLL patients allowed precise localization of the rearrangements in individual patients. As a result, genome rearrangements were localized on a map of EcoRI/HindIII digestion sites with a resolution of 1-2 kb (Y. Liu et al. 1995). Such a resolution cannot be obtained by FISH or LOH analysis. Rearranged genomic DNA fragments were observed in three out of 206 B-CLL patients examined in the Karolinska Hospital, Sweden. The minimal area of overlap between deletions in these three patients was only 10 kb. In 46% of cases (95 out of 206 tumor DNA specimens), deletions of the 10-kb region affected either both chromosomes (28 cases) or only one (67 cases) (Y. Liu, M et al. 1997). Interestingly, the minimally deleted region identified in this study was located upstream of D13S319 (i.e., on its centromere side), whereas most other authors mapped the CLL TSG downstream of this marker.

### **Tumor suppressor gene candidates located in 13q14**

Through the efforts of various labs and researchers, a more informative physical map of the deleted region in CLL was subsequently generated. On this map, all deletions found in patients with B-CLL were mapped within the 620-kb interval between D13S1168 and D13S25. Interestingly, in some cases the minimally deleted regions

mapped by different research groups were not overlapping, in fact, in some cases these regions were located a hundred kilo-bases apart. These findings may be interpreted in three different ways: either there are multiple TSGs involved in CLL and are located in 13q14 (unlikely), either the expression of the B-CLL-associated TSG is sensitive to chromosome rearrangements in its vicinity, or that the B-CLL-associated gene is rather large, and consequently deletions in its first or last exon may similarly impair its function. In either case, identification of the TSG associated with B-CLL required the mapping of all RNA transcripts located within the 620-kb area of interest. This work started in 1996, when the process of mapping and initial characterization of transcripts was laborious. Hence, the first attempts to hunt down the CLL TSG were restricted to the analysis of the most probable candidates, located in the chromosome region most commonly eliminated by deletions.

### **DLEU1 and DLEU2**

Researchers used various different methods of mapping in an attempt to locate precisely the deleted regions in 13q14. Despite initial difficulties with positional cloning due to the unique features of this region such as unusually high content of repeats, researchers were able to compose a valuable picture. Independent studies by various labs produced the map of non-overlapping but adjacent minimally deleted regions (MDRs) (Fig.1). Two candidate tumor suppressor genes, DLEU1 and DLEU2, were suggested as a result of the analysis of the smallest (10kb) MDR region et al. 1997). Nucleotide sequencing of DLEU1 and DLEU2 did not reveal homology to any known genes. The

putative open reading frames of DLEU1 and DLEU2 seem to encode for hypothetical proteins of only 72 and 84 residues, respectively. The open reading frames of DLEU1 and DLEU2 are associated with weak Kozak sequence context, casting doubts on their ability to function as translated proteins. Single-strand conformational polymorphism (SSCP) analysis of these ORFs and adjacent non-coding sequences did not reveal any point mutations in samples from B-CLL patients (Y. Liu, M et al. 1997; Migliazza, A et al. 2001). In-depth analysis into DLEU1 showed it to be a fragment of a much larger 560-kb gene thought to contain at least 50 exons and be expressed as up to 20 different non-coding RNAs. (S. Wolf et al. 2001). This gene was re-named BCMS (B-Cell Multiple Splicing) (S. Wolf et al. 2001).

The DLEU2 gene was also extensively studied. The extended sequence of this gene was deposited in GenBank in 2000 under the name BCMSUN (BCMS-Upstream Neighbor) (D. Mertens et al. 2000). Like DLEU1, DLEU2 is expressed as multiple alternatively spliced RNAs lacking reading frames. Interestingly, despite the DLEU2 ortholog being present in the mouse genome, human and mouse RNA isoforms of DLEU2 only have a few exons in common, (B. Kapanadze et al. 2000) thus indicating that the 13q14 region harboring the putative CLL TSG underwent relatively recent rearrangements in the course of evolution. Despite a number of interesting findings describing peculiar expression patterns of the first line candidates DLEU1 and DLEU2, a lack of open reading frames and presence of mutations in the DNA of CLL cells prompted the removal of these genes from the list of likely CLL TSG candidates.

## MicroRNAs

The obvious absence of protein coding genes within the minimal deletion in CLL cells initiated an exhaustive search for non-coding sequences with regulatory potential in CLL. A recent study examining the expression profiles of microRNAs and the ability of these profiles to help distinguish normal B cells from malignant B cells in CLL, found that there indeed was a unique microRNA change associated with 13q14.3 deletions. The microRNA genes miR-15a and miR-16-1 were located to the 30-kb core of the minimally deleted region (Calin et al. 2005; G.A. Calin et al. 2002). MicroRNAs represent a new class of gene products that are typically excised from 60- to 70-nt fold-back RNA precursor structures by Dicer RNase III and the Argonaute family members (T.P. Chendrimada et al. 2005). Interestingly, miR-15a and miR-16-1 are down-regulated or deleted in the majority of B-CLL cases. In addition, a clearly identifiable band of 70 bp was seen in many CLL samples, suggesting that miR-15a might be inefficiently processed in some CLLs (G.A. Calin et al. 2002). On the other hand, a C->T homozygous substitution was detected in premiR-16-1 in 2 out of 75 screened CLL patients, but in none of the 160 normal subjects. In both of these CLL patients, normal cells from the buccal mucosa were heterozygous for this abnormality. Therefore, the C->T change is a germ-line mutation; the mother and sister of one of these patients had CLL and breast cancer, respectively, supporting the possible causal role of this mutation in predisposition to CLL (G.A. Calin et al. 2005) as opposed to sporadic CLL.

MiR-16-1 is a member of the family of miRNA-16-like genes which share sequence identity, so it would be extremely difficult to study the trans-regulation effects

of miR-16-1 located in 13q14 apart from the effects of its paralogues. Collectively, the miR-16 family down-regulates a number of targets located on various human chromosomes and causes an accumulation of cells in G(0)/G(1) (P.S. Linsley et al. 2007). To what extent this cell cycle block depends on the individual effect of miR-16-1 remains unknown. Both miR-15 and miR-16 were shown to negatively regulate Bcl2 at a post-transcriptional level and induce apoptosis (G.A. Calin et al 2006). Recently, the genome of the CLL model animal, the New Zealand black (NZB) mouse, was shown to have a point mutation in the 3' flanking sequence of the orthologous microRNA, miR-16-1. This mutation is not present in other strains, including the nearest relative, the New Zealand white (NZW) mouse. A decrease in the levels of miR-16 was noted in NZB lymphoid tissue (E.S. Raveche et al. 2007; B.J. Scaglione et al. 2007). All these findings suggest that alteration of the normal expression suppressor function of miRNAs located within 13q14 is intimately linked to CLL.

Interestingly, the same RNA molecules that encode pre-miRNA may exert additional cis-regulatory effects on other genes located in 13q14, as they are located within the area covered by the DLEU2/miR-15a/miR-16-1 transcript described above. This very complex transcription unit overlaps with the RFP2/KCNRG/RFP2OS unit described in the following chapters.

## **RFP2**

*RFP2* (Ret Finger Protein 2) (Kapanadze et al. 1998; Baranova et al. 2004) is situated 10 kb away from the minimal deletion region (Fig. 1). Its open reading frame encodes a

protein of 407 amino acid residues and contains zinc-binding RING domains, a B-box, and a coiled-coil domain (A. Baranova et al. 2003). This combination of domains is known as the RBCC/TRIM domain and is found in a number of Rfp-like proteins which take part in cell differentiation, regulation of early embryo development, immune response, and neoplastic transformation. As a general rule, RBCC/TRIM domain-containing proteins appear to function as parts of large protein complexes and possess E2-dependent E3 ubiquitin ligase activity (K.M. Short and T.C. Cox, 2006). RFP2 has been shown recently to encode an unstable protein with autopolyubiquitination activity. (M Lerner 2008). Rfp2 protein interacts with other proteins localized to the endoplasmic reticulum (ER) and is involved in the ER-associated degradation (ERAD) pathway, which serves as a primary mean of quality control within the secretory pathway and decreases ER stress by clearing terminally mis-folded proteins from the ER (M. Lerner et al. 2007).

Despite its promising location, no mutations were found in *RFP2* during screening of patients with CLL (A.Baranova, 2003; Migliazza, A et al. 2001; van Everdink WJ et al. 2003). Additionally, direct sequencing of *RFP2* revealed no mutations in six patients and four multiple myeloma (MM) cell lines harboring 13q14 deletions (M.O. Elnenaei et al. 2003). These findings decrease the probability that *RFP2* is actually a tumor suppressor gene. However, a study of *RFP2* has revealed many interesting features of that locus which might be relevant to CLL, as they point to the unexpectedly high complexity of this expressed region of chromosome 13. This region proved to be transcribed in both directions, as *RFP2* overlaps with at least two anti-sense RNAs

encoded by the opposite DNA strand, *DLEU2* (M.M Corcoran et al. 1991) and *RFP2OS* (A. Baranova et al. 2003). Furthermore, the *RFP2* promoter contains multiple quadruplex forming GGGGA-repeats and possesses very low nucleosome-forming potential, allowing for its unusual strength (M. Skoblov et al. 2006)

The *RFP2/LEU5* transcript may be alternatively spliced to yield either a monocistronic transcript or a theoretically predicted bicistronic transcript encoding two separate open-reading frames. Furthermore, the *DLEU2* gene may produce a noncoding antisense RNA, whereby one of its exons, previously described as *RFP2OS*, directly overlaps the first exon of the *RFP2/LEU5* gene in the opposite orientation (Corcoran et al. 2004; Baranova et al. 2004). *RFP2* may be involved in the activation of the NF- $\kappa$ B pathway, implicating this region within the chromosome in various disease pathways (Matsuda et al. 2003).

## **KCNRG**

The gene *KCNRG* is located adjacent to *RFP2* and is thought to encode a potassium channel regulating protein (Ivanov et al. 2003). Due to the close proximity of these two genes it is not clear whether *KCNRG* mRNA is transcribed using a promoter in the *RFP2* 3' untranslated region, or whether *RFP2* and *KCNRG* share a promoter. *KCNRG* encodes two protein isoforms *KCNRG-L* (272 aa) and *KCNRG-S* (229aa), corresponding to variant 1 and variant 2 respectively (Fig.2); Previous studies showed differential expression of *KCNRG* mRNA isoforms between tumor and normal cells (Ivanov et al. 2003). Isoforms S and L were found in normal human lungs, in lymphocytes and in

prostate cells, however they were not found in the cell line LNCaP which is a prostate cancer cell line. In the ovarian cancer cell line SKOV-3 and osteosarcoma cell line T1-13, expression of KCNRG was not found at all. Interestingly, in the A431 epidermoid carcinoma the levels of expression of the larger mRNA isoform were decreased compared to other samples, and in the osteosarcoma cell line SAOS-2, larger of two mRNA isoforms can not be detected by amplification.

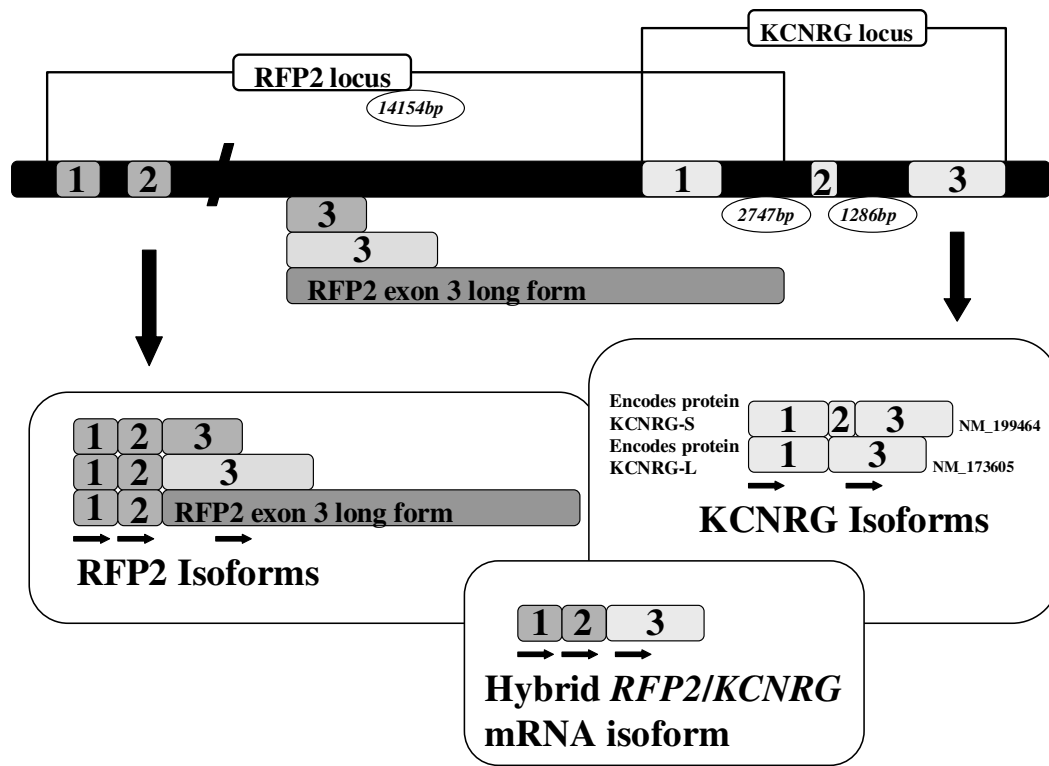

Fig.2. Isoforms of KCNRG and RFP2 and overlapping regions

KCNRG exerts an inhibitory effect on Kv potassium channels (Ivanov et al. 2003). It encodes a protein which resembles the T1 (tetramerization) domain of the voltage gated K<sup>+</sup> channels, suggesting that the protein encoded by KCNRG may interfere

with the normal assembly of these channels and thereby suppresses Kv currents (Ivanov et al. 2003).

Potassium channels are one of the most varied members of the ion channel family, and generally can be divided into two broad categories: the 'delayed' group and the 'transient' group (Perney T.M et al. 1991; Luneau C et al. 1991; Stuhmer W et al. 1989). The diversity found in potassium channels is thought to be caused by small amino acid changes that affect not only the voltage-dependent gating mechanism, but that also modify other properties such as channel conductance and the ability of channels to interact with various toxins. The understanding of the regulatory processes of K<sup>+</sup> channels is a constantly expanding field and includes mechanisms of plasma membrane depolarization, hyper-polarization, actions of intracellular kinases, and actions of GTP binding proteins and various other second messengers (Schwarz T.L et al. 1988).

K<sup>+</sup> channels can be further categorized into two classes based on their trans-membrane topology: the six trans-membrane helix voltage gated (Kv) class, and the two trans-membrane helix inward rectifier (Kir) class (Papazian DM et al. 1987, Pongs O et al. 1988, Ho K et al. 1993). All K<sup>+</sup> channels possess a distinct sequence (TMxTVGYG) between two trans-membrane helices at the carboxy-terminus (Heginbotham L. et al 1994). The trans-membrane region of the Kv channel, containing tetrameric components is composed of the  $\alpha$ -subunits which form a pore (Fig. 3). Each of these  $\alpha$ -subunits contains six hydrophobic trans-membrane units: S1, S2, S3, S4, S5, S6 with a P-domain inserted between S5 and S6 (Sansom MS, 2000). S1, S2, S3, S5 and S6, are thought to function in the closing and opening of the pore whereas unit S4 is thought to be the

voltage sensing component in these channels, and is not exposed to the lipid bilayer (Miller C., 2000).

Fig. 3: Kv Shaker type channel with  $\alpha$ ,  $\beta$  and T1 domains.

The Kv type of potassium channel can be further subdivided based on sequence similarity and function into four classical subfamilies: Kv1 (Shaker), Kv2 (Shab), Kv3 (Shaw) and Kv4 (Shal) (Miller C., 2000). All Kv channels, however, have a highly conserved T1 domain whose function is still being elucidated but is thought to be involved in determining the subfamily specific assembly of the alpha-subunits and shares homology with proteins that contain a BTB/POZ domain (Bixby K.A. et al. 1999).

The T1 domains in eukaryotic Kv channels seem to serve as a link, via the S1 subunit, between the pore forming units and the B subunit (Gulbis JM et al. 2000; Sewing S et al. 1996; Yu W et al. 1996). Although emerging research seems to not only indicate

an additional regulatory function in terms of channel gating but also seems to suggest that the conformation of the T1 domain influences the operation of the channel itself (Wang G et al. 2006; Cushman SJ et al. 2000; Minor DL. et al. 2000). The B subunit is a tetrameric arrangement of proteins that are thought to be related to aldo-keto reductase enzymes (Rehm H. et al. 1988; Parcej DN et al. 1992; Scott VE et al. 1994; McCormack T. et al. 1994; Chouinard SW. et al. 1995; Gulbis JM et al. 1999). Although more and more features of the B subunit structure and composition are being elucidated, its exact function remains elusive (Long SB et al. 2005).

In addition to the classical roles of K<sup>+</sup> channels such as their involvement in neural signaling, generation of cardiac rhythm, signal transduction pathways via G protein coupled receptors; K<sup>+</sup> channels are now thought to play a crucial role in cell cycle processes, apoptosis and cancer (Attali B et al. 1992; Felipe A et al. 2006). In fact, Kv channels are being implicated in a diverse range of diseases and metabolic pathways. In a recent study Kv channels were proposed to play a role in pulmonary arterial hypertension (PAH), which is an antiapoptotic, proliferative, and inflammatory disease (Bonnet S et al. 2007). A recent study on breast cancer proposed a definite connection between Kv channels and deregulation in apoptosis in certain types of breast tumors (Brevet M et al. 2008). Additional regulatory roles for Kv channels have been proposed where the Kv channels play a role in proliferation by maintaining the driving force for calcium influx (Cahalan MD and Lewis RS, 1990).

These new roles for Kv channels open up a vista of possible mechanisms by which KCNRG can play a role in B-CLL formation. Primary among these is KCNRG

dependent suppression of Kv currents that affect calcium-dependent cell cycle control. For example, Kv channels were previously implicated in metastasis and proliferation of hepatocarcinoma cells. In these cells the blockage of Kv channels prevents both adhesion and proliferation (Zhou Q et al. 2003).

Despite the promising advances on the characterization of KCNRG, there has yet been no evidence of KCNRG mutations in B-CLL cases sampled. This suggests that perhaps a new approach needs to be adopted when attempting to determine the characteristics and effects of KCNRG.

### **Haploinsufficiency**

Finding a somatic point mutation in the majority of a tumor of a given type is commonly considered a final proof of the involvement of a candidate gene in tumor suppression. However, in some cases, point mutations of a gene clearly capable of tumor suppression in both *in vitro* and *in vivo* experimental settings are never or almost never found in tumor DNA samples. During the last five years the haploinsufficiency mechanism of tumor suppressor gene inactivation has come to be the focus of many cancer-related studies (M. Santarosa and A. Ashworth, 2004). According to this model, inactivation of one copy of the tumor suppressor gene via deletion or methylation is enough to provide selective advantage or prevent apoptosis in progenitor cells of the tumor. Often in such cases tumor cells contain a large chromosomal of one copy of the gene while the second copy remains intact with no point mutations. This might indeed be the case with CLL, since non-imprinting type of the monoallelic silencing of genes

localized in the critical region has been observed (D. Mertens et al. 2000). Therefore, deletion of the single active copy of 13q14.3 may result in significant down-regulation of the candidate genes and loss of their function (D. Mertens et al. 2000; D.V. Ivanov et al. 2003). The involvement of the haploinsufficient genes in the process of tumorigenesis cannot be proven by mutation screenings showing that both copies of TSG are inactivated by one or another mechanism, but requires thorough functional studies.

There are several examples of diseases in particular, cancers that arise due to haploinsufficiency. An example of such a case is acute myeloid leukemia where the haploinsufficiency of the gene AML1 instigates the genetic cause of the disease (Barton K and Nucifora G., 2000). Another piece of information which supports the haploinsufficiency approach is the observation that in cases of haploinsufficiency often the gene in question is dramatically down-regulated in disease samples. Although mutations were not shown in RFP2, several genes including RFP2 were shown to be consistently downregulated in B-CLL patients, and furthermore RFP2 was the most significantly downregulated gene (Mertens et al. 2000). Unfortunately KCNRG was not examined at this time as this gene was not known, however the adjacent location of these two genes, and the detection of their fusion mRNA isoforms suggest that RFP2 and KCNRG may be co-regulated. Downregulation of KCNRG was mentioned during the study of its expression in cancer cell lines (Ivanov et al. 2003).

A recent study on hepatocellular carcinoma (HCC) was conducted by analyzing the mutation, allelic loss and expression pattern of the KCNRG gene as well as performing in vitro assays. Interestingly, the outcome of the study did indeed indicate an

allelic loss of KCNRG in HCC, but more importantly, the results seem to indicate a correlation between allelic loss and severity of disease. Moreover, one somatic missense mutation c.275G>A (p.R92H) and a lower frequency (26.5%) of allelic losses were found in the Korean population of informative HCC cases. As the corresponding normal sample showed no evidence of mutations by repeated SSCP analysis, the mutation was likely a somatic event. Interestingly, the HCC case with a KCNRG mutation showed a LOH at D13S272 and only aberrant bands of the mutant allele as determined by SSCP, suggesting a mutation in one allele and loss of the other. The authors concluded that loss or alteration of the KCNRG gene may play a previously unforeseen role in the development and/or progression of some cases of HCCs (Cho YG et al. 2006).

### **13q14 deletions in other malignancies**

Many previously described human tumor suppressor genes play a role in the development of more than one type of human malignancy. The list of such polyfunctional TSGs includes TP53 (M. Olivier et al. 2004), PTEN (I. Sansal and W.R. Sellers, 2004), CDKN2A (N.E. Sharpless, 2005) and others. If the putative tumor suppressor for CLL is indeed located in 13q14.3, it might play a role in the development of other tumors harboring a deletion in this segment of the human genome.

Rearrangements and/or deletions in the region of 13q14.3 are found in many types of hematopoietic malignancies. These deletions account for 38% in mantle cell lymphoma (MCL) (Rosenwald et al. 1999; A. Cuneo et al. 1999), and approximately 54% in multiple myeloma cases (MM), as detected by FISH (Harrison C.J. et al. 2003;

Fiserova A. et al. 2002; M.O. Elnenaei et al. 2003; L. Chen et al. 2007). In the majority of these cases 13q14 deletions are associated with a poor chemotherapy response profile. Deletions of 13q14.3 could contribute to the development of overt leukemia in T-cell prolymphocytic leukemia (T-PLL) (V. Brito-Babapulle et al. 2001).

Allelic imbalance at 13q14.3 is an important event in the progression of localized prostate cancer (N. Brookman-Amissah et al. 2007) and in high-grade high-stage carcinoma originating from prostatic tissue (J.T. Dong et al. 2001). Interestingly, some studies indicate that 13q14 loss is also associated with the initiation of prostate tumors (W. Lu et al. 2006). The region within 13q14, distal to the RB1-locus, is of importance to the development of low-malignant lipomatous tumors (A. Dahlen et al. 2003).

A study of the KCNRG allelic loss in 13q14 revealed deletions in 13 (25.5%) out of the 51 HBV-positive HCCs of grade II and in 4 (66.7%) out of 6 HCCs of grade III. There was a significant correlation between an allelic loss and the histology grades ( $P = 0.0078$ ) and stages ( $P = 0.0071$ ). Furthermore, the number of allelic losses was higher in those cases with an intrahepatic metastasis than in the cases without metastasis ( $P = 0.0247$ ) (Y.G. Cho et al. 2006). Taken together, these observations indicate that the elusive TSG located in 13q14.3 may have an importance not limited to CLL. Therefore, all CLL TSG candidates discussed above should be subjected to both mutational screening and functional studies in the malignant cells of non-lymphatic origin.

## **Chapter 2: Materials and Methods**

### **Cloning and sequencing of human KCNRG**

The basic molecular biology and microbiology procedures such as plasmid isolation, cloning, *E. coli* transformation and cultivation, were performed according to standard protocols (Sambrook et al., 1989). Human KCNRG variant 1 and KCNRG variant 2 were cloned into a pcDNA3.1/myc-His vector (Invitrogen, San Diego, CA). The cloning of KCNRG variant 1 was performed by OriGene (Rockville, MD, USA). The cDNA used was a full-length archived cDNA clone which corresponds to the mRNA isoform NM\_173605. The cloning of KCNRG variant 2 was performed by our collaborators Andre Marakhonov and Dr. Mikhail Skoblov (Russian Center for Medical Genetics, Moscow, Russia) by amplifying its full length ORF from the coding sequence of human brain cDNA. This product was cloned into a pGemT-Easy vector (Promega, Madison, WI), and then transferred into a pcDNA3.1/myc-His plasmid. According to the manufacturer's protocol, bidirectional sequencing of the plasmids and PCR clones with vector or gene-specific primers were performed by fluorescence-tagged chain termination (Big Dye Terminator, Applied Biosystems) and the fragments detected using a ABI 310 automated DNA sequencer (Applied Biosystems).

The recombinant plasmids containing KCNRG V1 and KCNRG V2 were stored at -80 until transformation. The *E. coli* strain used for transformation was JM109, standard K-12 non-pathogenic *recA*<sup>-</sup>, *endA*<sup>-</sup> *E. coli* appropriate for routine cloning

applications. JM109 cells contain the LacI<sup>q</sup>ZΔM15 gene on the F' episome, allowing blue-white screening for recombinant plasmids.

Following transformation the *E. coli* cells were grown on imMedia™ Amp Agar for selection and imMedia™ Amp Liquid for propagation (Invitrogen, CA). The plasmids were extracted using EndoFree Plasmid Maxi Kit (QIAGEN).

### **HL-60, RPMI-8226 and LNCaP cells stably expressing KCNRG V1 and KCNRG V2**

Cell lines LNCaP, HL-60 and RPMI-8226 were obtained from the American Type Culture Collection (Manassas, VA). LNCaP cells are androgen-sensitive human prostate adenocarcinoma derived from the lymph node metastasis. They are adherent epithelial cells growing in aggregates and as single cells. Functional differentiation of LNCaP cells is preserved. HL-60 (human promyelocytic leukemia) cell line proliferates continuously in suspension culture with the doubling time of about 36-48 hours. HL-60 cells are predominantly a neutrophilic promyelocyte (precursor). RPMI-8226 is a multiple myeloma cell line with lymphoblast-like appearance.

All of the cells were grown and maintained in RPMI1640 media containing 2 mM glutamine, 10 mM HEPES and 10% fetal calf serum (Invitrogen, CA). Transfections of the cell lines were initially attempted using a liposome-mediated transfection system, Lipofectamine™ Reagent (Invitrogen) according to the manufacturer's protocols. Optimization of transfection conditions was performed with positive control lacZ-containing vector provided with the pcDNA.3.1/myc-His/ system. Despite the

manufacturer's claims of low toxicity, transfection reactions with Lipofectamine (Invitrogen) yielded stable transfectants only with RPMI-8226 cells. A very high rate of cell death was observed for mock-Lipofectamine transfected cells (designated: EV for empty vector pcDNA.3.1/myc-His) for the first days following transfection, indicating high levels of reagent toxicity. This was most evident in HL60 cells, in which none of the transfectants survived the first week of transfection regardless of the minimal concentrations of the transfectant.

Following this discovery, a less toxic system was deemed necessary, and consequently the cDNA-containing or empty control plasmids were transfected into LNCaP, HL-60 and RPMI-8226 cells with Transfectol reagent (Gene Choice, Frederick, MD). This transfection system was optimized to yield the highest number of transfectants and the lowest number of cell deaths due to toxicity. After the cells were transfected, they were incubated in growth media containing RPMI1640 media with 15% fetal calf serum for 24 hours to aid their recovery. Following the recovery period cells were centrifuged and re-suspended in RPMI1640 media with 10% fetal calf and a selection specific antibiotic. Stably transfected cells were selected using 500 ug/mL of Geneticin (Sigma) and were subsequently maintained in 75 cm<sup>2</sup> flasks in medium with antibiotic in incubators with 5% CO<sub>2</sub> and humidity for the duration of the experiments. The continual growth of cells in selective antibiotic assured the maintenance of selective pressure and prevented the loss of the transfected plasmid.

## **HL-60, RPMI-8226 and LNCaP cells transiently expressing KCNRG V1 and KCNRG V2**

The same transfection reagents were used for the preparation of the transiently transfected cells. The transfection was carried out in a 96 well plate as per the manufacturer's instructions. In addition to the empty vector plasmid, KCNRG V1 plasmid and KCNRG V2 plasmid, cells were mock transfected using only the Transfectol reagents to determine toxicity effects of the reagents. The transiently transfected cells were immediately used for experiments 48 hours after transfection and were not selected with Geneticin.

### **Generation of Clonal Populations**

Following stable transfection, a serial dilution of the mixed cell populations was performed on a 96-well cell culture plate in an attempt to isolate and generate a clonal population. RPMI-8226 was the only cell line in which this was successfully achieved, as LNCaP and HL60 cells did not survive being isolated into single cell units. Forty three clones were generated for the RPMI-8226 cell line; out of these three clones were selected based on their rate of proliferation as compared to the mixed population: fast growing (S1B9), same as mixed population (S2A11), and slow growing (S3A10).

### **Cell proliferation and apoptosis assays**

Cell proliferation assays were performed using the Chemiluminescence-based Cell Proliferation ELISA, BrdU kit (Roche). The chemiluminescence-based assay was

chosen as it has been found to be more sensitive than its colorimetric version (Unteregger G, Profit S., 2001).

Proliferation rates of the cells transfected with empty vector and stable KCNRG variant 1 and 2 overexpressing cells were determined by quantifying the BrdU incorporated into the newly synthesized DNA of replicating cells. The experiment was conducted according to the manufacturer's protocol. The cells were seeded into 96-well black plates with clear bottoms (Thermo Electron) at a density of  $2 \times 10^4$  per well. Cells or blanks (100  $\mu$ L) and 10  $\mu$ L of the BrdU labeling solution were added to the wells. The incubation time was determined experimentally. Due to the longer replication periods of the transfected cells, the optimum time for BrdU incorporation in HL60 and RPMI-8662 was 48 hours and the optimal time for LNCaP was 72 hours. Each cell type was tested in replicates of eight. Chemoluminescence was quantified using a Fluoroskan Ascent microplate fluorometer (Thermo Scientific).

To determine apoptosis in KCNRG V1, V2 and empty vector transfected cells, the Caspase-Glo® 3/7 Assay was used (Promega, Madison, WI). This assay focuses on the caspase-3 and -7 activities and the level of caspase activity in the sample is proportional to the luminescence produced by caspase cleavage of the substrate. For the apoptosis assays, cells were seeded in 96-well black plates with clear bottoms (Thermo Electron) at a density of  $3.5 \times 10^4$  per well in 50  $\mu$ L of RPMI1640 media with 10% fetal calf serum. As per the manufacturer's protocol, the Caspase-Glo reagent was added in a 1:1 ratio. All of the cell lines were incubated for 2 hours at room temperature and chemoluminescence was quantified using a Fluoroskan Ascent microplate fluorometer (Thermo Scientific).

In experiments where the cells were transiently transfected, immediately following transfection proliferation and apoptosis assays were performed using conditions identical to those of the stable transfection experiments. The only exception to this protocol was the addition of an extra set of 16 wells with mock-transfected cells. Chemoluminescence was quantified as described above.

### **FACS / flow cytometry**

Cell cycle distribution was analyzed by flow cytometry (Kim Y. et al 1992). All of the cell lines were grown to optimum densities. Cells were brought to concentrations of  $1.5 \times 10^6$  cells/mL and were transferred to 15 mL conical tubes. Cells were washed twice with cold PBS, centrifuged at 1000g for 5 min and resuspended in 1 mL of PI staining solution (PBS + 50ug/mL PI + 100ug/mL RNase A). Cells were incubated at 4°C in the dark for 20 minutes and were analyzed on FACSCalibur (Becton Dickinson) within 15-30 minutes of staining. All of the cells were kept on ice and away from light during the entire experiment.

Quantification of cell death was determined by staining with Annexin V/7-AAD kit (BD Pharmingen, San Jose, CA). Annexin V aids in the detection of one of the primary events in apoptosis, namely, the translocation of the membrane phospholipid phosphatidylserine (PS) from the inner surface to the outer surface of the plasma membrane. This allows for Annexin V, a 35-36 kDa,  $\text{Ca}^{2+}$ -dependent, phospholipid binding protein to bind to PS. However, since translocation of PS also occurs during necrosis, 7-amino-actinomycin (7-AAD), which binds to nucleic acids only in the case of

a failure in the membrane integrity was used in conjunction with Annexin V. The dual use of Annexin V and 7-AAD aided in clearly establishing the population of cells going through apoptosis versus those going through necrosis. Cells were once again counted and prepared in densities of  $1.5 \times 10^6$  cells/mL. All of the cells were washed and the centrifuged pellets were re-suspended in 0.1mL of 1x binding buffer, 10  $\mu$ L of annexin V and 5  $\mu$ L of 7-AAD were added to each sample. Cells and reagents were gently mixed and incubated at room temperature for 15 minutes in the dark. Following incubation 0.9 mL of 1x binding buffer were added to the cells. The samples were analyzed within 1 hour of staining. Controls stained with Annexin V only and 7-AAD only were performed for calibration purposes. During the experiments cells were kept on ice and away from light sources.

### **Cell Imaging**

Cells were stained with fluorescent dyes in an attempt to visualize any morphological changes that may have been caused by transfection with KCNRG V1 and KCNRG V2. With this goal in mind, three regions of interest on the cell were observed. DAPI, a blue-fluorescent nucleic acid stain was selected to stain the nucleus (Invitrogen). DAPI preferentially stains dsDNA and is believed to associate with the AT clusters in the minor groove (Kubista M et al. 1987). When DAPI binds to dsDNA it produces a ~20-fold fluorescence enhancement, which is thought to be due to the displacement of water molecules from DAPI and the minor groove (Tanious FA et al. 1992). DAPI has also been successfully used in conjunction with other dyes, and when used according the

manufacturers protocols, stains nuclei specifically. The plasma membranes were stained with 3-diiododecylcarbocyanine perchlorate (DiOC18) (Invitrogen). DiOC 18 is highly lipophilic and can diffuse laterally through out the membrane and most importantly does not influence the viability of the cells (Zhang W et al 2005). Hence it was deemed optimal for observing minute morphological changes in the membrane structures of the cell, be it plasma membrane or inter cellular membranes. The third goal of the fluorescent imaging of the cells was to determine the overall changes in the structure of the cells. As such, Rhodamine phalloidin was used to visualize the F-actin content of the cells. Rhodamine phalloidin is a phalloxin, a bicyclic peptide which is isolated from the deadly *Amanita phalloides* mushroom and has a very high affinity to F-actin filaments (Wieland T., 1977). Phalloxins stabilize F-actin filaments, thereby preventing depolymerization while retaining functionality and overall structural integrity of the cell (Mahaffy RE et al. 2008; Oda T et al. 2005).

RPMT-8662 and HL60 cells were centrifuged and the cell pellets rinsed with PBS to remove media components. The cells were fixed in freshly prepared 4% paraformaldehyde/PBS solution for 15 min at room temperature. Cells were permeabilized by adding 0.1% Triton-X100 in PBS for 1 min. A PBS diluted solution of Rhodamine-phalloidin (1:100 in PBS), 5  $\mu$ L of 300 nM DAPI and 4  $\mu$ L of diluted DiOC 18 solution were added to the permeabilized cells. The mixture was incubated for 15 min at room temperature. Following staining the cells were rinsed in PBS three times and mounted onto slides with coverslips. LNCaP cells were grown directly on cell culture treated slides and were washed and consequently treated in the same manner as the other

two cell lines. Slides were kept in the dark and in the freezer until imaging. Images were taken on a Nikon Eclipse 90i microscope equipped with a Nikon C1 confocal scan head and laser lines at 406nm, 488nm and 568nm.

### **Invasion and migration assays**

To evaluate the migratory and invasive properties of the cells over-expressing KCNRG, fluorimetric CytoSelect 96well Cell Migration and Invasion, CytoSelect 24-wells Anoikis and CytoSelect Leukocyte Transmigration Assays (Cell Biolabs, Inc, San Diego, CA) were used according to the manufacturer's protocols. The CytoSelect™ 96-well Cell Migration Assay Kit uses a polycarbonate membrane chamber (8  $\mu$ M pores) as a barrier to separate cells with the ability to migrate from cells that are non-migratory. This platform is based on the ability of migratory cells to extend protrusions towards chemo-attractants via cellular processes such as microfilament reorganization thereby passing through the pores of the membrane. Once through the membrane, these migratory cells are dissociated from the membrane and detected with CyQuant® GR Dye. A similar theory underlies the platform for the invasion assay where an insert membrane, coated with a layer of dried basement membrane matrix solution is used to separate cells that have the ability to degrade matrix proteins and therefore the ability to pass through the membrane from those that do not have these abilities. Due to the larger pore size of these assays HL60 cells were not tested with this assay, but instead were tested using the CytoSelect Leukocyte Transmigration Assays (Cell Biolabs, Inc, San Diego, CA) which

not only has a smaller pore size, but also has an endothelial monolayer of cells which provides additional information on the cells ability for extravasation.

An anoikis assay was performed on the LNCaP cells to observe any changes in apoptosis resulting from the loss of cell adhesion to the extracellular matrix (ECM). The CytoSelect™ 24-Well Anoikis Assay uses a poly-Hema coated plate in conjunction with a cell culture control plate and allows the measurement of cell viability using either MTT or Calcein AM. MTT (3-(4, 5-dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide) is a yellow tetrazolium salt that is reduced by metabolically active cells and is used in determining cell proliferation. Calcein AM is an acetomethoxy derivate of calcein and is transported through cellular membranes of live cells, upon binding to calcium within the cell it emits a strong green fluorescence signal thereby “labeling” only live cells. Levels of anoikis related cell death is measured by ethidium homodimer (EthD-1), a red fluorescent dye that can penetrate only damaged cell membranes. Upon binding to ssDNA, dsDNA, RNA, oligonucleotides, and triplex DNA, EthD-1 fluoresces with a 40-fold increase. This property also causes a fairly low background as the dye has almost no fluorescence in its non-bound state.

A cell suspension of  $2 \times 10^6$  cell/mL in culture media was prepared. Cell suspension (0.5 mL) was added to each well of the anchorage resistant plate and the 24 well control plate. The cells were cultured for 72 hours at 37°C and 5% CO<sub>2</sub>. As per the manufacturers protocol, 50 µL of the MTT Reagent was added to each well of the anchorage resistant plate and control plate. The plates were incubated for 2 hours at 37°C. Following incubation 500 µL of detergent solution was added to each well and mixed.

The plates were covered and incubated for an additional 2 hours at room temperature. An aliquot (200  $\mu$ L) of each sample was transferred to a 96-well plate and the absorbance was determined at 570 nm (Fluoroskan Ascent, Thermo Scientific).

For the Calcein AM / EthD-1 Fluorometric Detection, 1  $\mu$ L of Calcein AM/EthD-1 solution was added to each well of the 24-well anchorage resistant plate and the control plate. These plates were incubated for 30 minutes at 37°C. The cells were microscopically observed for the presence of the green Calcein AM (Ex: 485 nm and Em: 515 nm) or red EthD-1 (Ex: 525 nm and Em: 590 nm) for fluorescence. The fluorescence was also read quantitatively with a fluorescence microplate reader (Fluoroskan Ascent, Thermo Scientific).

### **Proteome analysis**

The protein analysis was performed by our collaborators at the Center for Applied Proteomics & Molecular Medicine. Amy J. VanMeter prepared the samples. For reverse-phase protein microarrays the protein lysates were loaded into 384-well plates and each lysate was serially diluted in lysis buffer to a 5-point dilution curve (neat, 1/2, 1/4, 1/8, and 1/16). Each dilution series was printed in duplicate onto nitrocellulose-coated glass slides (Whatman, Inc., Sanford, ME) with a 2470 Arrayer (Aushon BioSystems, Burlington, MA). Slides were dessicated and stored at -20°C. Before antibody staining, the lysate arrays were treated with mild Reblot Antibody Stripping Solution (Chemicon, Temecula, CA) for 15 minutes at room temperature, washed twice for 5 minutes in phosphate buffered saline, and then incubated for at least 5 hours in blocking solution [1g

I-block (Tropix, Bedford, MA), 0.1% Tween-20 in 500 ml phosphate-buffered saline] at room temperature with constant rocking.

Blocked arrays were stained with antibodies on an automated slide stainer (Dako Cytomation, Carpinteria, CA) using the Catalyzed Signal Amplification System kit according to the manufacturer's recommendation (CSA; Dako Cytomation). The endogenous biotin was blocked for 10 minutes with the biotin blocking kit (Dako Cytomation). This was followed by application of protein block for 5 minutes. The primary antibodies were diluted in antibody diluent and incubated on slides for 30 minutes, and the biotinylated secondary antibodies were incubated for 15 minutes. Signal amplification was achieved by incubation with a streptavidin-biotin-peroxidase complex provided in the CSA kit for 15 minutes, and amplification reagent, (biotinyl-tyramide/hydrogen peroxide, streptavidin-peroxidase) for 15 minutes each. Development was completed using diaminobenzadine/ hydrogen peroxide as the chromogen/substrate. Slides were then allowed to air dry. Primary antibodies (n = 38) were specifically chosen to be analyzed to cover the broad signaling pathways thought to be involved in the proliferation and apoptosis-related signaling. Secondary antibodies and dilutions included: biotinylated goat antirabbit IgG (H<sub>L</sub>) 1:5,000 (Vector Laboratories, Burlingame, CA); and biotinylated rabbit anti-mouse IgG 1:10 (Dako Cytomation).

Stained slides were scanned individually on a UMAX PowerLook III scanner (UMAX, Dallas, TX) at 600 dpi and saved as TIF files in Photoshop 6.0 (Adobe, San Jose, CA). The TIF images for antibody stained slides and SYPRO-stained slide images were analyzed using MicroVigene image analysis software, version 2.200 (Vigenetech,

North Billerica, MA), and Microsoft Excel 2000 software. The images were imported into Microvigene, which was used for spot finding, local background subtractions, replicate averaging, and total protein normalization. This analysis produced a single value for each sample at each endpoint.

### **Pathway -Specific Microarray Gene Expression Profiling**

Two separate experiments with pathway specific microarrays were performed, the Oligo GEArray® Human Cancer Microarray (OHS-802) and the Oligo GEArray Human Hematopoietic Stem Cells and Hematopoiesis Microarray (OHS-054). The general protocol for both of these arrays was the same and proceeded as follows.

Cells were grown to confluency and  $1 \times 10^6$  cells were counted and separated. RNA was extracted using RNeasy RNA extraction kits (Qiagen) according to the manufacturer's protocol. The RNA concentration and purity were determined by UV spectrophotometry (GeneQuant). RNA extractions were verified to have a  $A_{260}:A_{280}$  ratio greater than 2.0 and a  $A_{260}:A_{230}$  ratio greater than 1.7. In addition, aliquots of the extracted RNA samples were run on an agarose gel to visually determine a clear distinction between the 18S and 28S ribosomal RNA (rRNA) bands and that the sample did not have any smearing indicating sample degradation.

According to the manufacturer's protocol an annealing mixture was prepared using 3.0  $\mu$ g RNA and 1.0  $\mu$ L Component G1. The volume was brought to 10  $\mu$ L by the addition of RNase-free water. The mixture was mixed and briefly centrifuged and incubated at 70°C for 10 min. Following the incubation, the mixture was again

centrifuged briefly (~2 sec) and was immediately placed on ice. A cDNA synthesis master mix was prepared by combining 4  $\mu$ L of RNase-free water, 4  $\mu$ L of 5X cDNA Synthesis Buffer (G3), 1  $\mu$ L of RNase Inhibitor (RI) and 1  $\mu$ L of cDNA Synthesis Enzyme Mix (G2) to a final volume of 10  $\mu$ L. The master mix solution was mixed, briefly centrifuged and placed on ice. A cDNA synthesis reaction was made by adding 10  $\mu$ L of cDNA synthesis master mix solution to each tube which also contained 10  $\mu$ L of annealing mixture. The tubes were mixed gently by pipetting several times and were briefly centrifuged. Each sample was incubated at 42 °C for 50 minutes followed by 75 °C for 5 minutes and then cooled to 37 °C. The amplification master mix was prepared on ice by adding 16  $\mu$ L of 2.5X RNA Polymerase Buffer (G24), 2  $\mu$ L of Biotinylated-UTP (10 mM) and 2  $\mu$ L RNA Polymerase Enzyme (G25) into a final volume of 20  $\mu$ L. The cRNA Synthesis Reaction was prepared by add 20  $\mu$ L Amplification Master Mix to each tube containing 20  $\mu$ L of cDNA Synthesis Reaction. The solutions were mixed, centrifuged and were incubated overnight at 37 °C. Purification of the samples was performed using spin columns. The cRNA was bound to the spin column by adding 60  $\mu$ L of RNase-free water to each cRNA synthesis reaction tube to bring the volume to 100  $\mu$ L. Contents of the tubes were transferred to a 1.5 mL RNase-free tube. Lysis & Binding Buffer (G6; 350  $\mu$ L) was added to each reaction mixture followed by 350  $\mu$ L of room temperature ACS-Grade 100% ethanol. Contents were mixed and loaded to the spin columns. Spin columns were centrifuged for ~ 30 sec at 8,000 x g and the flow through solution was discarded. The columns were washed in several consecutive steps by adding 600  $\mu$ L Washing Buffer (G17 with ethanol), centrifuging for ~ 30 sec at 8,000 x g and

adding another 200  $\mu$ L Washing Buffer (G17 with ethanol) and centrifuging for 1 min at 11,000 x g. The cRNA was eluted into a fresh RNase-free tube by adding 50  $\mu$ L of room temperature RNase-free 10 mM Tris buffer pH 8.0 (G26). The filter was allowed to soak completely by incubating at room temperature for 2 min. This was followed by centrifugation for 1 min at 8000 x g. The resultant samples were stored on ice. The cRNA concentration was determined by UV Spectrophotometry (GeneQuant).

A pre-hybridization step was performed by adding 2 mL of pre-warmed GEAhyb Hybridization Solution to each filter array and incubating for 30 minutes at 60 °C with shaking at 500 rpm on the GEMatrix® Express Thermoshaker. A target hybridization mix was prepared by adding 4  $\mu$ g cRNA target to a 2.0 mL aliquot of warm GEAhyb Hybridization Solution. Each sample target was added to a separate hybridization chamber containing a GEMatrix® and was sealed with a GEMatrix® Multi-Chamber Seal. The arrays were incubated for 24 hours at 60 °C with shaking at 500 rpm. Arrays were rinsed with 4 mL of pre-warmed Wash Solution, followed by 2 mL of pre-warmed Wash Solution 2 and incubated for 5 min at 60 °C with shaking at 1000 rpm. The wash buffer was removed and the arrays were allowed to reach room temperature. Dilute AP-Streptavidin (2 mL) was added to each GEMatrix® and incubated for exactly 10 min on the bench top. This solution was removed and 2 mLs of room temperature 1X Buffer F was added and arrays were incubated for 5 min at 37 °C with shaking at 700 rpm; this step was repeated three times.

To perform the buffer equilibration 2 mL of room temperature Buffer G was added and the arrays incubated for ~ 1 minute at 37 °C with shaking at 700 rpm. Buffer G

was removed and 1.0 mL of CDP-Star®, was added and the arrays incubated with shaking at 37 °C for 1 min. Upon the removal CDP-Star® the arrays were incubated in the HybPlate without shaking at 37 °C for 4 minutes. Immediately following this incubation the GEMatrix® chemiluminescent images were acquired using a cooled CCD camera system (Kodak). The images were saved in TIFF format, and the array filters were allowed to dry and were stored in sealed plastic packets. Spot finding and spot intensity measurements were performed with the integrated GEMatrix Expression Analysis Suite (SuperArray).

### **Real-time PCR profiling of KCNRG in human lymphoma samples and cell lines**

Total RNA was isolated by Qiagen RNeasy Mini Kit (Valencia, CA) from wild-type cell lines LNCaP, HL-60 and RPMI-8226 (ATTC, Manassas, VA) as well as from their derivatives stably expressing KCNRG V1, KCNRG V2 and the pcDNA3.1 empty vector control. Reverse transcription reactions were performed using 2 µg of total RNA. Reactions were heated at 70 °C for 5 min in a total volume of 12.5 µL in the presence of 100 ng of random hexamers (Invitrogen) and cooled at room temperature for 1 min. After a mini-centrifuge spin, 4 µL of 5X first strand buffer (Invitrogen), 2 µL of 0.1 M DTT and 0.5 µL of 25 mM dNTP mix (Fisher Scientific) were added to the reaction. The mixture was then incubated at 42 °C for 1 h. The resulting cDNA was stored frozen (-80 °C) until assayed by real-time PCR.

In addition to KCNRG primers, primers for genes selected from the analysis of the microarray data were used to perform real-time PCR reactions in a 96-well format in

the BioRad iCycler iQ RealTime Detection System (BioRad Laboratories, Hercules, CA)(Table 1). The real-time PCR mixtures contained 1  $\mu$ L of the reverse transcribed RNA sample, 400 nM each of forward and reverse primers and 1X iQ SYBR Green Super Mix and were carried out in a total volume of 15  $\mu$ L. Amplification of 18S RNA in parallel with the genes of interest was performed as an internal control as described (Grace et al., 2003). For each gene of interest and 18S RNA, three-to-four independent PCR experiments from the same RT sample were performed.

To further confirm microarray data a pathway focused gene expression profiling real-time PCR system was used (RT2 Profiler™ PCR Array System, SuperArray). The RT2 Profiler PCR Array Human Apoptosis pathway was selected based on the number of overlapping genes between the RT-PCR platform and the microarray platform. The 96-well array platform consisted of wells A1 through G12 containing a real-time PCR mix for genes from the same biological pathway, wells H1 through H5 containing housekeeping genes for normalization, well H6 containing a genomic DNA control, wells H7 through H9 containing replicate reverse transcription controls and wells H10 through H12 containing replicate positive PCR Controls. The genomic DNA was eliminated in each 5 µL sample by adding 2.0 µL of GE (5X gDNA Elimination Buffer) and bringing the final volume to 10.0 µL with RNase-free water. An RT-PCR reaction cocktail was

prepared per sample by adding 4  $\mu\text{L}$  of 5X RT buffer (BC3), 1  $\mu\text{L}$  of primer and external control mix (P2), 2  $\mu\text{L}$  of RT enzyme mix (RE3), and 3  $\mu\text{L}$  of RNase-free H<sub>2</sub>O. The RT cocktail (10  $\mu\text{L}$ ) was added to each of the 10  $\mu\text{L}$  genomic DNA elimination mixtures and was incubated at 42 °C for 15 min followed by heating at 95 °C for 5 minutes in order to degrade the initial RNA and to inactivate the reverse transcriptase. Following inactivation 91  $\mu\text{L}$  of ultra-pure water was added to each 20  $\mu\text{L}$  of cDNA synthesis reaction and solution was stored on ice. The RT-PCR assay mixture was prepared for a 96-well format by adding 1275  $\mu\text{L}$  of 2x SuperArray RT<sup>2</sup> qPCR master mix, 102  $\mu\text{L}$  of diluted first strand cDNA synthesis reaction, and 1173  $\mu\text{L}$  of ddH<sub>2</sub>O for a final volume of 2550  $\mu\text{L}$ . The reaction mixture (25  $\mu\text{L}$ ) was added to each experimental well of the 96-well assay and sealed with the film provided. The RT-PCR was performed on the BioRad iCycler iQ Real-Time Detection System according to the manufacturers protocol (BioRad Laboratories, Hercules, CA).

To assess KCNRG gene expression in human lymphoma samples, TissueScan Tissue qPCR Arrays Panels were purchased from OriGene Technologies, Inc (Rockville, MD). The normalized cDNAs per each panel were composed of 6 normal, 10 follicular lymphomas, 11 diffuse large B-cell lymphomas, 3 small lymphocytic lymphomas, 6 Hodgkin lymphomas, 8 marginal zone B-cell lymphomas, 2 mantle cell lymphomas and 3 T-cell lymphomas (Table 2). Reactions were performed in a 96-well format in 30  $\mu\text{L}$  volumes in the BioRad iCycler iQ Real-Time Detection System (BioRad Laboratories, Hercules, CA). The cycling program for the reaction was determined experimentally for the previously mentioned KCNRG primers. For KCNRG isoforms, three independent

PCR experiments on individual pre-normalized Tissue Scan plates from the same manufacturer's batch were performed. As an additional control,  $\beta$ -actin mRNA levels were also tested in triplicate. The presence of a single, specific PCR product was verified by melting curve analysis and confirmed on agarose gels.

## Computer programs and statistic analysis

Comparative analysis *in silico* and an analysis of the structure of the KCNRG gene were performed using genomic, mRNA and EST databases

(<http://www.ncbi.nlm.nih.gov> and <http://genome.ucsc.edu>). The KCNRG promoter was predicted by Core Promoter (<http://www.cshl.edu/OTT/html/corepromoter.html>) and NNPP ([http://www.fruitfly.org/seq\\_tools/promoter.html](http://www.fruitfly.org/seq_tools/promoter.html)) services. Multiple alignments of the protein sequences were performed using ClustalW v.1.83. A phylogenetic tree of prealigned T1 domains of KCNRG-like proteins was reconstructed by the neighbor-joining method and visualized by the same software. Group comparisons were performed by non-parametric Mann-Whitney hypothesis tests. Unless otherwise noted, P values < 0.05 were considered significant.

A novel method for the analysis of the dual channel microarray data was developed by James Baughman. The microarray dataset was analyzed by normalization based on the average of the selected gene expressions across all of the arrays. Selected genes were picked from the built in list of ‘housekeeping’ genes provided by the SuperArray oligo platform. Genes were selected based on their performance as true housekeeping genes, and their ability to accurately indicate the signal intensity of their representative arrays. Therefore, the sensitivity of individual gene expression in the control arrays (HR1, HR2,...) versus the arrays with transfected genes (HT1, HT2,...) is highlighted vis-à-vis this normalization method. The method does not take into account the selected gene expression within the array, but rather uses the overall variance of selected gene expression across arrays as a means to quantify the comparative expression of each individual array. Normalization was based on the following process: The mean of the selected gene expression for each array was calculated ( $\mu_1$ ,  $\mu_2$ ,  $\mu_3$  ...). The mean of the selected gene expression of all arrays ( $\mu_T$ ) was then calculated. The expression of

each gene (selected & non-selected) was multiplied by the mean selected gene expression of all arrays divided by the mean selected gene expression of its array ( $[\mu_T / \mu_1]$ ,  $[\mu_T / \mu_2]$ ,  $[\mu_T / \mu_3]$ ...). This was normalized by dividing by the mean expression of each array (selected & non-selected) and multiplying the result by 100. The minimum expression was set at 10.

## Chapter 3: Results and Discussion

### Comparative analysis of the KCNRG mRNA and protein isoforms

Candidate tumor suppressor gene KCNRG resides within the 3' end of the largest transcript of human RFP2 gene described earlier (Baranova et al., 2003; Lerner et al., 2007). Major mRNA isoforms of KCNRG are transcribed independently of RFP2, starting at the promoter located within 3'-untranslated region RFP2 (Fig.2). This sequence coincides with the *in silico* predicted promoter located in the position approximately –100 nt upstream of the putative 5' end of the KCNRG transcripts according to an alignment of the KCNRG ESTs to the genomic sequence (Core Promoter score 1.000, NNPP score 0.97).

Additionally, collaborators at the Russian Center of Medical Genetics (RCMG) demonstrated an existence of a hybrid mRNA isoform that includes exons from both RFP2 and KCNRG (Fig.2) (M.Skoblov, personal communication). This isoform originates from the quadruplex containing promoter of RFP2, possibly due to its unusual properties described earlier (Skoblov et al., 2006). In all examined species of mammals with the exception of human and chimps, KCNRG and RFP2 genes are encoded by separate loci (Fig.4).

#### Human *RFP2* and *KCNRG*:

#### Rat *Trim13* and *Kcnrg*:

#### Mouse *Trim13* and *Kcnrg*:

**Fig. 4.** Comparative analysis of the RFP2/KCNRG locus found in human, rat and mouse genomes. Exons are shown as boxes and introns or intergenic regions as lines. Exons of RFP2 or its orthologs (Trim13 in mouse and rat) are depicted in black while exons of KCNRG and its orthologs are illustrated in gray. Sizes are scaled to the human genome distances.

Human KCNRG encodes two protein isoforms KCNRG-L (272 aa) and KCNRG-S (229aa), corresponding to variant 1 and variant 2 respectively, that differ in their C-ends and possess common N-end of 184 aa. A T1 tetramerization domain covers amino acid positions 7 to 98. KCNRG loci of other mammals including chimpanzee, encode only one protein isoform corresponding to human KCNRG-L. In chimps, KCNRG-L differs from its human ortholog by one amino acid substitution (Pro→Leu) in the position 158. Comparison of human and rat KCNRG orthologs revealed 85.4% identity in a 268 residue overlap, while comparison with the mouse ortholog was characterized by 73.2%

identity in a 264 residue overlap. Murine KCNRG locus encodes two protein isoforms, 264 and 191 residues in length, both of which are variants of human KCNRG-L isoform.

Interestingly, human KCNRG-S and KCNRG-L isoforms share only the first 191 residues, while being different in their C-termini. This difference is due to out-of-frame insertion of the alternatively spliced exon 2 that is present only in the human genome and is derived from an AluSp SINE repeat. According to results of RT-PCR experiments performed by colleagues in RCMG, RAMS (data not shown) mRNA isoforms encoding two KCNRG proteins are co-expressed in human tissues. Levels of Alu-containing KCNRG-S mRNA isoforms are substantially lower than that of KCNRG-L mRNA.

### **Computational analysis of the KCNRG protein**

Computational analysis of the sequence of KCNRG was performed in order to discern any regions of interest within its open reading frame. The amino acid sequences of KCNRG-L (272 aa) and KCNRG-S (229) aa isoform have been used for a blastp search against the protein database. The data resulting from this blastp analysis were examined to determine the highest matching sequences. The highest matching sequences were obtained using the (E) values calculated from the blastp search. The (E) value is a parameter that refers to the possible expected number of hits one can obtain from searching a given database, this value decreases as the significance of the hit increases. Hence the lower the (E) value, the stronger the match.

The resulting data were tabulated and separated into two sets in accordance with the region of homology. The first set comprised the sequence similarity between amino

acids 1 and 190. This segment of the sequence displayed two regions thought to be conserved domains: the BTB/POZ domain with an (E) value of  $8e-7$  and a K<sup>+</sup> channel tetramerization domain with an (E) value of  $9e-14$  (Fig.5). The data presented in the following homology analysis were obtained using the shorter of the two isoforms (229 aa).

**Fig.5.** The regions of KCNRG containing conserved domain homology

The BTB/POZ (The BTB (for BR-C, ttk and bab, and the POZ also known as poxvirus and zinc finger) domain consists of a protein-protein interaction motif located at the N-termini of certain transcription factors as well as certain types of potassium channels. The structure is comprised of a tightly intertwined dimer created by the interactions between the N-terminal strand and helix structures (Bardwell et al. 1994 and Koonin et al. 1999). The cytoplasmic tetramerization domain (T1) of voltage-gated K<sup>+</sup> channels, also known as K<sup>+</sup> tetramerization domain, is thought to code for the molecular components used for the subfamily-specific assembly of the alpha-subunits into functional tetrameric channels. It is also thought to be related to the BTB/POZ domain (Kobertz et al. 1999 and Zerangue et al. 2000). Using a molecular visualization program, images of the Kv channels can be generated and the locations of the tetramerization domains can be seen with respect to the rest of the channel (See Fig. 6) (Kobertz et al. 1999).

**Fig.6.** RASMOL image of a view along the four-fold axis of the T1 domain tetramer. Yellow designates the Asn 167 side chains that form the tightest constriction along the axis. Red marks the C-termini that attach to the channel protein ~20 residues before the beginning of the S1 transmembrane helix. (Kobertz et al. 1999).

Interestingly, detailed blastp analysis of the shorter version of KCNRG protein (isoform S, 229 aa in size) revealed a novel, very highly conservative domain located between amino acids 190 and 229. As no known conserved domain signatures were recognized in this region, we considered this domain as novel and called it COOL (because we think it is very interesting - “cool”, and because it’s located close to C-end). The list of the proteins homologous to the C-tail of KCNRG isoform S includes those that belong to protein families with various functions. COOL domains with the proposed structure most closely resembling that of C-end of KCNRG-S isoform are found in human serine-threonine kinase STK2 (NIMA-type kinase 4), protein BCAS4 that is often amplified or fused in breast carcinomas and TRIM61/RNF35 RING finger protein that is translated temporally in the pre-implantation embryos (Hayashi et al., Barlund et al., Choo et al.). Nucleotide analysis of the exon encoding the COOL-domain suggests its

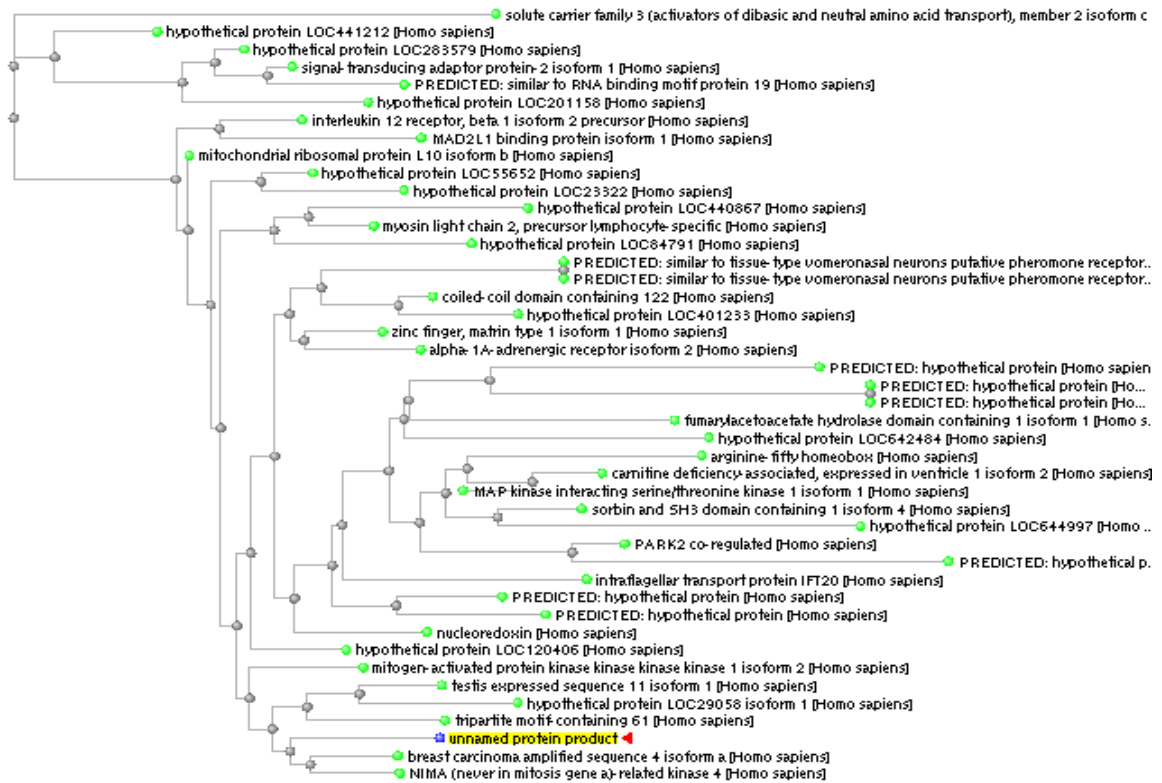

possible origin from the insert of a partial Alu-repeat into the 3' area of its open reading frame.

The complete list of the COOL domain containing proteins and corresponding alignments can be found in Appendix 1, 2 and 3. The preliminary analyses of the COOL proteins indicate no clues as to functions. This domain may serve regulatory functions, e.g. it may contain an important site for post-translational modification or protein-protein interaction.

According to Motif Scan analysis ([http://scansite.mit.edu/cgi-bin/motifscan\\_seq](http://scansite.mit.edu/cgi-bin/motifscan_seq)) both KCNRG isoforms are with high probability able to interact with SH3 domains of Amphiphysin, Cbl-Associated protein C, and IL2-inducible T-cell kinase ITK/LYK (also known as PSCTK2, ETK) (Fig.7). Both Serine/threonine-protein kinase STK2/Nek4/NRK2 and BCAS4 proteins that include COOL-like domains also contain a SH3 binding site. The same site is also present in a variety of the potassium voltage-gated channel proteins.

Analysis using the NetPhos 2.0 Server indicated possible phosphorylation sites at 5 Ser, 3 Thr and 2 Tyr residues, with one of the Ser phosphorylation sites located within the COOL domain. Four highly significant O- $\beta$ -GlcNAc attachment sites, 3 of them located in the COOL domain were predicted using the YinOYang 1.2 server (<http://www.cbs.dtu.dk/services/YinOYang/>). A search for a short protein motif performed by ELM (Eukaryotic Linear Motif Resource, <http://elm.eu.org/>) revealed, among others, a highly conserved SSDSPA motif that is embedded within COOL domain. According to ELM, SSDSPA motif is classified as Class IV WW domain

interaction motif involved in phosphorylation-dependent interactions. The complete list of the motifs and functional sites found in KCNRG can be found in Appendix 4.

**Fig.7.** Fast minimum evolution tree of KCNRG COOL-domain.

## KCNRG is a member of the KCTD protein family

Human KCNRG is a member of the KCTD gene family that encodes predicted proteins with an N-terminal domain that is homologous to the T1 domain in voltage-gated potassium channels. The KCTD family of proteins belong to a larger group of non-channel T1/BTB proteins. KCTD family members are similar to Pfam K\_tetra consensus (PF02214) rather than that of BTB/POZ (Stogios et al., 2005). Our analysis (Fig.8 and 9)

**Fig. 8.** An alignment of KCNRG with other proteins of KCTD family. Degree of shading indicates different degree of conservation for a given amino acid position: invariant positions are darkest, other conserved positions are shaded lighter, non conserved positions are not shaded. Total length of T1 domain, its position and full length of the proteins are summarized in the table adjacent to the aligned protein sequences. Truncated versions of T1 domain are marked by star (\*).

**Fig. 9.** A phylogenetic tree of prealigned T1 domains of KCNRG-like proteins.

revealed two additional KCNRG-like proteins that should be classified as KCTD family members, TNFAIP1 (Tumor necrosis factor- $\alpha$ -induced protein 1) and SHKPB1 (SH3KBP1 binding protein 1), while the protein C6orf69 previously classified as KCTD20 represents an out-group and should be excluded from the T1 family in a *sensu stricto*.

Previous research has implicated TNFAIP1 in the progression of cancer and linked its overexpression to increased rates of apoptosis (Yang LP et al. 2006). An interesting study on HBV showed increased TNFAIP1 expression via RT-PCR detection in patients that are immune to HBV, indicating a role for TNFAIP1 in the innate immunity against HBV (Lin MC et al. 2005). Recently a study of a comparative genome-scale transcriptional analysis of two T-cell subsets CD4<sup>+</sup> and CD8<sup>+</sup> against each other and against CD3<sup>+</sup> cells found TNFAIP1 to be one of the set of proteins implicated in the communication between these two subsets, indicating a possible role for TNFAIP1 in T-cell activation and immune response (Wang M et al. 2008).

SH3KBP1, a gene with many alternative names (Gene names: SH3KBP1, CIN85, Protein names: Human Src family kinase-binding protein 1 (HSB-1), CD2-binding protein 3 (CD2BP3), Cbl-interacting protein of 85 kDa) encodes an adapter protein involved in regulating diverse signal transduction pathways ([UniProt](#), Watanabe S et al. 2000). Recent studies have implicated SH3KBP1 in ASAP1 mediated EGF receptor recycling, leading the investigators to propose a scaffold protein role for SH3KBP1 (Kowanetz K et. al 2004). Additionally, another study has shown that SH3KBP1 interacts

with TNFR1, leading to the hypothesis that this association may modulate TNF- $\alpha$ -induced apoptosis (Narita T et al. 2005).

KCTD20 is a BTB/POZ domain-containing protein residing on chromosome 6p21.31 ([GeneCards](#)). It has been identified as part of a complex containing MARK4. This complex regulates microtubules, participates in the defining of the cell polarity and has a higher expression level in human gliomas (Beghini A et al. 2003; Brajenovic M. et al. 2004). KCTD13 (located on 16p11.2), alternatively known as FKSG86 and PDIP1, is a TNFAIP1-like protein, and interacts with POLD2 and PCNA. A role has been proposed for it in cytokine activation and DNA replication (He H et al. 2001). Similarly, like other TNFAIP1-like proteins, KCTD10 (12q24.11) is inducible by TNF- $\alpha$  and interacts with the small subunit of DNA polymerase delta and PCNA (Zhou J et al. 2005).

KCTD7 is located on 7q11.21 and is thought to be a cytoplasmic protein. Interestingly in a study attempting to shed light on the identity of the causal gene in autosomal recessive progressive myoclonic epilepsy (PME), linkage analyses identified a new locus on 7q11.2, where researchers found a C to T mutation in exon 2 of the KCTD7 gene (Van Bogaert P et al. 2007).

Recent research has found KCTD11 (also known as REN), located on 17p13.1, to play a regulatory role in neuronal differentiation via signaling by retinoic acid, epidermal growth factor/EGF and NGFB/nerve growth factor (Gallo R et al. 2002). Additionally, studies of medulloblastoma (MB) tumors revealed that KCTD11 suppresses the tumor-promoting Hedgehog signaling pathway, while in granule cell progenitors overexpression of KCTD11 seems to increase apoptosis and decrease proliferation (Di

Marcotullio L et al. 2004; Argenti B et al. 2005). A similar study of medulloblastoma samples found a reduction of KCTD11 expression in tumor cells as compared to normal adult cerebellum cells. Even more significant reduction of KCTD11 expression in neural stem cells lead the researchers to propose that haploinsufficiency of KCTD11 may play a role in MB tumorigenesis (Zawlik I et. al 2006). The most close paralogs for the KCTD11 gene include KCTD21 (11q14.1), KCTD15 (19q13.11), KCTD6 (3p14.3) and KCTD1 (18q11.2) a nuclear protein that has recently been found to act as a transcriptional repressor in addition to mediating protein-protein interactions through its BTB domain (Ding XF et al. 2008).

KCTD12, also known as Pftin, C13orf2, KIAA1778, and PFET1, is located on 13q22.3 and is paralogous to KCTD8 (4p13) KCTD16 (5q32) and KCTD14 (11q14.1) ([GeneCards](#)). KCTD12 was cloned from human fetal cochlear cDNA clones. Its 6-kb transcript was found to be present in several fetal organs, the highest expression levels being in the cochlea and brain; however very low expression levels were detected in adult tissues such as brain and lung (Resendes BL et al. 2004). A study aiming to find markers for transplantable bone marrow stromal cells (BMSCs) found KCTD12 to be a reliable indicator (Igarashi A et al. 2007). Recent research on type 2 diabetes (T2D), a Genome Wide Association (GWA) study identified new single nucleotide polymorphisms (SNPs) with 14 risk loci, one of these loci being KCTD12 (Cauchi S et al. 2008). A proteomic study aimed at developing prognostic biomarkers for gastrointestinal stromal tumors (GIST) found that KCTD12 was not only a strong marker for GISTs but was also

informative in distinguishing between GISTs with good and poor prognosis (Suehara Y et al. 2008).

KCTD3 (1q41) was found to be a tumor antigen recognized by the humoral immune system in a study with patients with renal cancer, thereby acquiring the name NY-REN-45 (Scanlan MJ et al. 1999). KCTD3 is co-expressed with the transcription factor Oct4 (Pou5f1) (with a % correlation of +91), a mediator that has been implicated in lineage specific differentiation, adult stem cell identity, and cancer (Pearl A et al. 2007).

KCTD9 is located on 8p21.1 and, in addition to the BTB/POZ domain, contains 3 pentapeptide repeat domains ([Uniprot](#)). Although detailed information on the function of KCTD9 has not yet been elucidated it has been independently identified in several cancer related array based genomic studies. These studies includes an attempt to determine signature genes distinguishing types or grades of tumors where KCTD9 was amongst the 10 most frequent genes as ranked by score (Junior Barrera et al. 2007).

A study on organ-confined prostate cancer observing whole genome copy number changes in the genomes of hormone-naïve lymph node metastases found KCTD9 to be amongst the genes exhibiting increased copy number aberrations (CNAs) for primary tumors that progressed and metastasized (Pamela L et al. 2006). In a study on sporadic breast cancer using array-based comparative genomic hybridization, researchers found KCTD9 to be amongst the genes with a 11.1% homozygous loss in the cell lines studied, and a 36% hemizygous loss in the tumors studied (Tara L Naylor et al. 2005).

Recently, KCTD5 (16p13.3) was found to interact with the adeno-associated virus 2 REP proteins (AAV-2 Rep78/Rep68) and upon interaction was found to undergo

translocation to the nucleus, thereby indicating a regulatory role for this protein (Weger S et al. 2007). In addition, new research has suggested that KCTD5 may also be a substrate-specific adaptor for cullin3-based E3 ligases (Bayón Y et al. 2008). Aside from their structural properties KCTD17 (22q12.3), KCTD18 (2q33.1), KCTD4 (13q14.12) and KCTD2 (17q25.1) have yet to reveal any functional properties.

Most of the KCTD proteins are relatively short (on average, 355 amino acids), their T1 domains are located close to the N-end of the protein and are not accompanied by any other Pfam domains. All KCTD proteins except KCTD19 contain only one T1 domain. The first of two T1 domains of KCTD19 is truncated. T1 domains of 3 out of 25 KCTD proteins (KCTD18, KCTD11 and KCTD9L) are truncated. KCNRG is a typical member of the KCTD family, with solitary T1 domain unaccompanied by any other recognizable protein structure. The function of these proteins is still unknown.

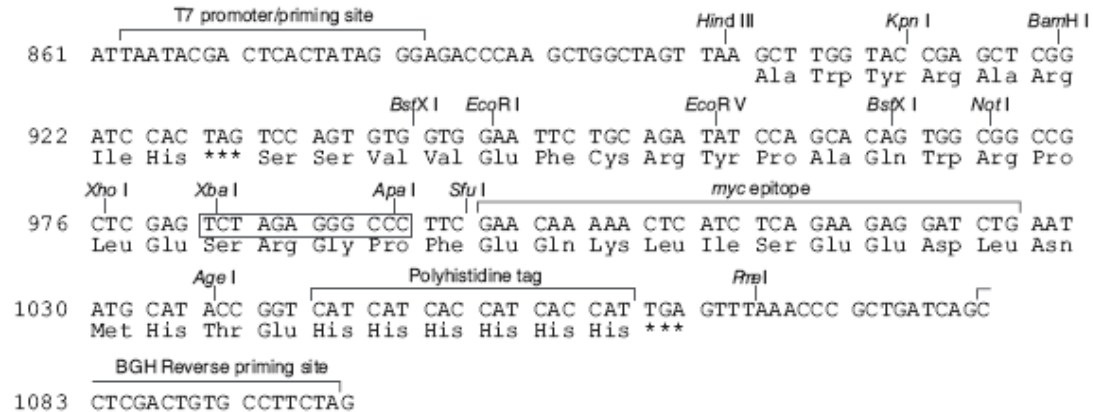

### **Cloning of KCNRG isoforms**

The initial cloning of KCNRG V1 was contracted to the Maryland based company OriGene. The company was provided with the pCDNA3.1/myc-His A vector (Invitrogen), the structure and multiple cloning site of this vector can be seen below (Fig.10).

### Multiple Cloning Site of Version A

Below is the multiple cloning site for pcDNA<sup>™</sup>3.1/myc-His A. Restriction sites are labeled to indicate the cleavage site. **Note that there is a stop codon between the BamH I site and the BstX I site.** The multiple cloning site has been confirmed by sequencing and functional testing.

**Fig. 10.** Multiple cloning site of pcDNA 3.1 version A (Invitrogen).

The KCNRG gene was cloned in between the BamH1 and Xho1 restriction sites.

The resulting recombinant plasmid obtained from OriGene can be seen below (Fig.11).

-BamH1--Start-

AATACGACTCACTATAGGGAGACCCAAGCTGGCTAGTTAAGCTTGGTACCGAGCTC\*GGATCC\***AGA**\*ATG\*AGT\*AGT\*CAG\*GAA\*CTG\*GTC\*ACT\*TTG\*AAT\*GTG\*GGA\*GGG\*AAG\*ATA\*TTTC\*ACG\*ACA\*AGG\*TTT\*TCT\*ACG\*ATA\*AAG\*CAG\*TTT\*CCT\*GCT\*TCT\*CGT\*TTG\*GCA\*CGC\*ATG\*TTA\*GAT\*GGC\*AGA\*GAC\*CAA\*GAA\*TTC\*AAG\*ATG\*GTT\*GGT\*GGC\*CAG\*ATT\*TTT\*GTA\*GAC\*AGA\*GAT\*GGT\*GAT\*TTG\*TTT\*AGT\*TTT\*ATC\*TTA\*GAT\*TTT\*TTG\*AGA\*ACT\*CAC\*CAG\*CTT\*TTA\*TTA\*CCC\*ACT\*GAA\*TTT\*TCA\*GAC\*TAT\*CTT\*AGG\*CTT\*CAG\*AGA\*GAG\*GCT\*CTT\*TTT\*TAT\*GAA\*CTT\*CGT\*TCT\*CTA\*GTT\*GAT\*CTC\*TTA\*AAC\*CCA\*TAC\*CTG\*CTA\*CAG\*CCA\*AGA\*CCT\*GCT\*CTT\*GTG\*GAG\*GTA\*CAT\*TTC\*CTA\*AGC\*CGG\*AAC\*ACT\*CAA\*GCT\*TTT\*TTT\*AGG\*GTG\*TTT\*GGC\*TCT\*TGC\*AGC\*AAA\*ACA\*ATT\*GAG\*ATG\*CTA\*ACA\*GGG\*AGG\*ATT\*ACA\*GTG\*TTT\*ACA\*GAA\*CAA\*CCT\*TCA\*GCG\*CCG\*ACC\*TTG\*AAT\*GGT\*AAC\*TTT\*TTT\*CCT\*CCT\*CAG\*ATG\*ACC\*TTA\*CTT\*CCA\*CTG\*CCT\*CCA\*CAA\*AGA\*CCT\*TCT\*TAC\*CAT\*GAC\*CTG\*GTT\*TTT\*CAG\*TGT\*GGT\*TCT\*GAC\*AGC\*ACT\*ACT\*GAT\*AAC\*CAA\*ACT\*GGA\*GTC\*AGG\*TAT\*GTT\*TCT\*ATA\*AAA\*CCT\*GAT\*AAC\*CGA\*AAA\*TTG\*GCC\*AAC\*GGA\*ACA\*AAT\*GTC\*CTC\*GGC\*TTA\*CTG\*ATT\*GAC\*ACT\*TTA\*TTA\*AAG\*GAA\*GGC\*TTT\*CAT\*TTG\*GTC\*AGC\*ACT\*AGA\*ACA\*GTA\*TCT\*TCT\*GAA\*GAC\*AAA\*AC

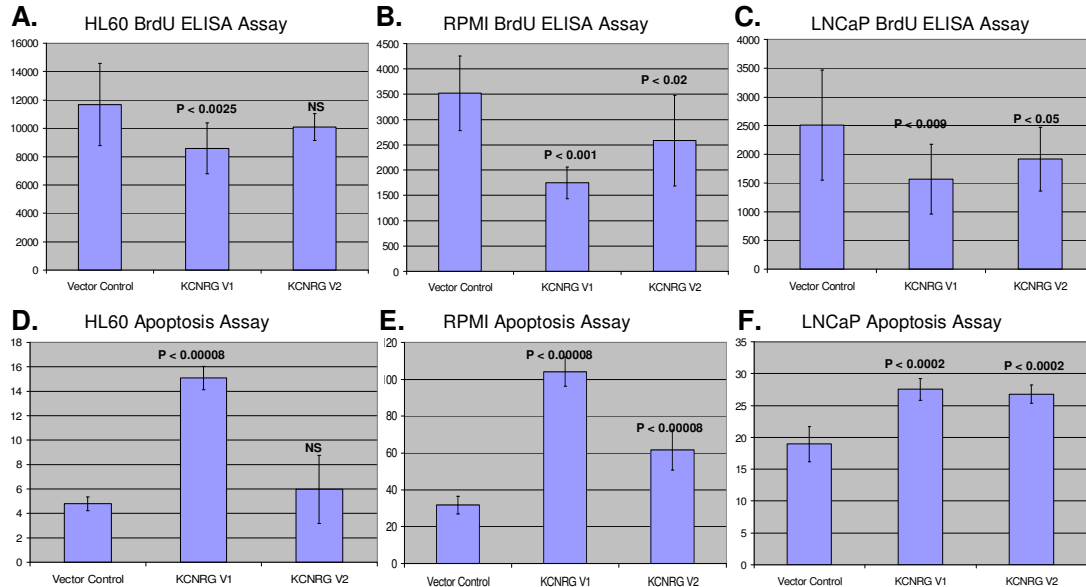

subjected to automated sequencing. Direct sequencing of KCNRG exons revealed a point mutation delT in the +30 position of the 5' non-coding area of KCNR gene in RPMI-8226 cell line (position indicated according to mRNA Ac. Num. NM\_199464). The search for known human SNPs was negative for any match in this nucleotide position. Interestingly, an analysis of matches to transcription factor binding matrices with MatInspector software revealed the core promoter initiator element (INR) that overlaps the mutated position. Deletion of T decreases the matrix similarity of the match from 0.945 to 0.941, and, therefore, might negatively influence expression of KCNRG in RPMI-8226 cells.

A low complexity repeat (A)<sup>33</sup>(TA)<sup>8</sup>(CA)<sup>8</sup>TATGTA(CA)<sup>2</sup>TACA(TA)<sup>4</sup>CA(TA)<sup>3</sup> located at the position – 1006 relative to the major start of KCNRG mRNAs and within 3' untranslated area of RFP2 was amplified by PCR with subsequent band resolution in polyacrylamide gel in 21 DNA sample of CLL patients and 50 DNA samples of normal donors at RCMG, RAMS. Unusually high levels of the polymorphism have been observed, as the profiling of a total of 142 chromosomes revealed 12 alleles of this repeat. The heterozygous state of this repeat was seen in 52/71 (73%) samples tested indicating high informativeness of this polymorphic DNA marker. In the future this marker can be used to test possible monoallelic losses of KCNRG gene in CLL samples.

### **Expression of KCNRG inhibits proliferation and enhances apoptosis in cultured tumor cells**

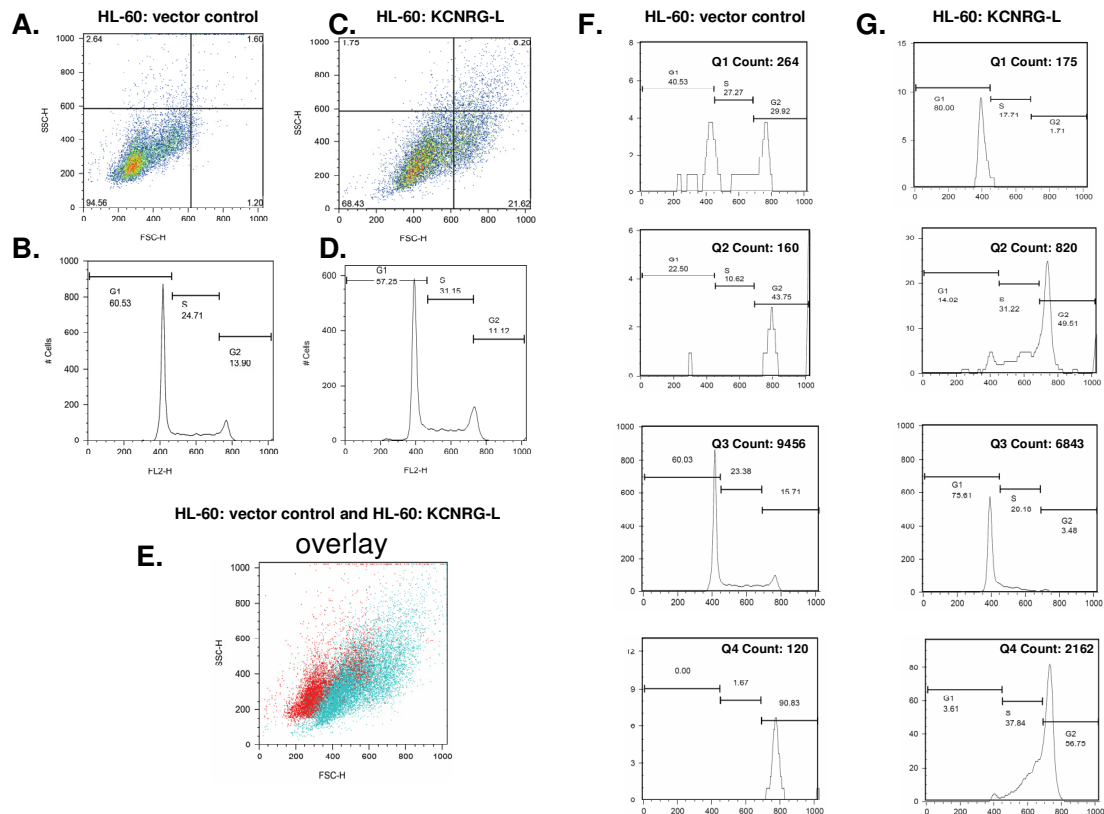

Open reading frames corresponding to both protein isoforms of KCNRG were cloned into the pcDNA3.1 backbone, stably transfected in to LNCaP, HL-60 and RPMI-

8226 cells and studied in various functional assays. The cells transfected with pcDNA3.1 vector alone were used as a control and are designated as EV for Empty Vector. As quantified by chemiluminescent BrdU cell proliferation ELISA assay, growth of all three cell lines was significantly inhibited by an overexpression of KCNRG-V1 isoform (RPMI-8226: decrease of 37%,  $P < 0.001$ ; HL-60: decrease of 26%,  $P < 0.0025$ ; LNCaP: decrease of 38%,  $P < 0.009$ ). The KCNRG-V2 isoform exerted less prominent growth suppressive effect in these cells (RPMI-8226: decrease of 27%; HL-60: decrease of 12%; LNCaP: decrease of 24%). In the case of KCNRG-V2 isoform, the difference between observed values were significant only for KCNRG-V2 overexpression in LNCaP ( $P < 0.05$ ) and RPMI-8226 ( $P < 0.02$ ) (Fig. 12 a,b,c).

**Fig. 12.** Expression of KCNRG inhibits proliferation (BrdU ELISA assay, A, B, C) and enhances apoptosis (caspase 3/7 assay, D, E and F) in cultured tumor cells. A and D: HL-60. B and E: RPMI-8226. C and F: LNCaP. Complete tables can be found in Appendix 6.

Cell survival was analyzed by measurement of the activities of caspases 3 and 7. An increase in the apoptotic events was found in the cells that were stably transfected with any KCNRG isoform, but in KCNRG-V1 cells these changes were more profound (KCNRG-V1/RPMI-8226: increase of 180%,  $P < 0.0008$ ; KCNRG-V1/HL-60: increase of 216%,  $P < 0.0008$ ; KCNRG-V1/LNCaP: increase of 46%,  $P < 0.0002$ ; KCNRG-V2/RPMI-8226: increase of 94%,  $P < 0.0008$ ; KCNRG-V2/HL-60: increase of 25%, NS; KCNRG-V2/LNCaP: increase of 41%,  $P < 0.0002$ ) (Fig. 12 d,e,f). Complete tables can be found in Appendix 6.

**Fig. 13** A. HL60 empty vector control in Side Scatter (SSC) vs. Forward Scatter (FSC) plot. B. Histogram of HL60 EV control C. HL60 transfected with KCNRG V1 in Side Scatter (SSC) vs. Forward Scatter plot. D. Histogram of HL60 transfected with KCNRG V1. E. Overlay of scatter plot for HL60 empty vector control and HL60 V1. F. Histogram analysis of each quadrant of HL60 empty vector control scatterplot. G. Histogram analysis of each quadrant of HL60 V1 scatterplot.

Observations described above were confirmed by FACS analysis of the cell lines over expressing KCNRG isoforms and the vector control (Figs. 13).

Interestingly, the suppression of the proliferation of the suspension cell lines HL-60 and RPMI-8226 has been accompanied by the dramatic changes in the size and the shape of the cells. An increase of KCNRG-V1 expression in HL-60 cell line resulted in the formation of two cell populations, a normal-like population mainly residing in G1 phase (Fig. 13F and 13G, quadrants 1 and 3) and larger, abnormal cells residing in G2 (Fig. 13F and 13G, quadrants 2 and 4). In order to see this effect more clearly the cells were analyzed by charting them on a SSC (Side Scatter) and FSC (Forward Scatter) plot (Fig. 13A and 13B). The plot was gated into four quadrants, and each cell line was subjected to the same gating conditions. The histogram of each quadrant clearly indicates more than one population of cells undergoing cell cycle changes. Similarly, an overexpression of KCNRG-V1 in RPMI-8226 also produced a population of abnormal cells (see Appendix 7) as compared to KCNRG-V2 and KCNRG-EV. The changes in LNCaP-V1 and V2 cells were more subtle, and composed mainly of a decrease in overall cell size for LNCaP-V1 cells, indicated by the slight shift downward of the scatter-plot (see Appendix 7). The quantification of the results for HL60 empty vector control and HL60 transfected with KCNRG V1 and V2 is presented in two tables (Fig. 14A and 14B), one summarizing the complete population, and one summarizing the gated populations (Tables summarizing PI FACS information on RPMI-8226 and LNCaP cell lines can be found in Appendix 7).

**A.**

**B.**

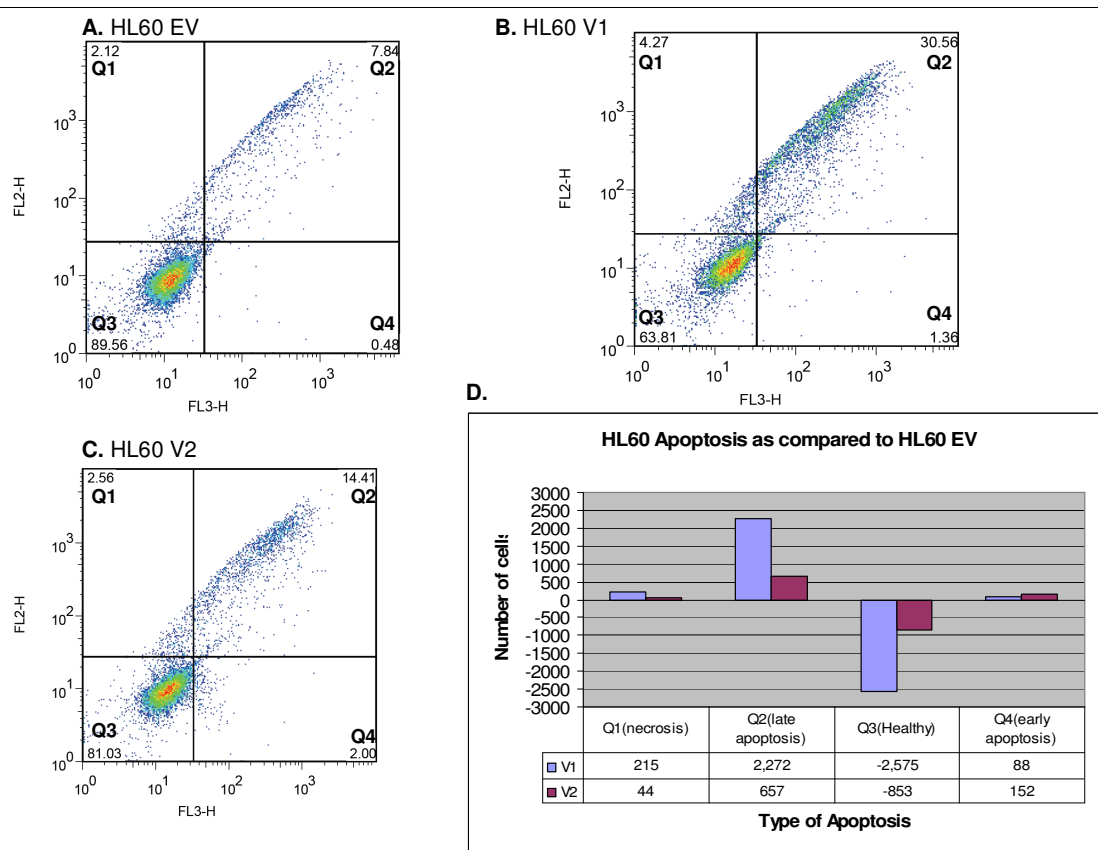

**Fig.14.** Quantification of HL60 EV and HL60 V1 scatterplots A. Quantification of non-gated data. B. Quantification of gated data.

The apoptosis data obtained by the chemiluminescent detection of caspase activity were also confirmed by FACS analysis using annexin V and 7-AAD. Quadrant 1 shows cells that have absorbed higher levels of 7-AAD, indicating cell wall disruptions, and therefore necrosis. Quadrant 2 shows cells that have absorbed equal amounts of annexin V and 7-AAD, and are cells at the stage of late apoptosis. Quadrant 3 shows healthy live cells, and quadrant 4 shows cells that have absorbed a larger amount of annexin V, indicating early apoptosis. HL60 cells transfected with KCNRG V1 have significantly higher levels of late apoptotic death (Fig. 15).

Interestingly, HL60 cells transfected with KCNRG V2 show slightly higher levels of early apoptosis, and slightly lower levels of necrosis as compared to the cells transfected with KCNRG V2 (See Fig. 15D). In addition, a slight but significant elongation of the healthy cell population can be observed in quadrant three for cell lines transfected with either isoform of KCNRG, once again indicating a more varied cell size in these populations (Fig. 15 A,B,C). The effects of KCNRG V1 and the trend towards increased late apoptosis was observed in RPMI-8226 and LNCaP cell lines as well, and can be found in Appendix 8.

**Fig. 15.** Scatterplots of annexin V and 7-AAD for FACS analysis of HL60 cells A. Scatterplot for HL60 empty vector control. B. Scatterplot for HL60 transfected with KCNRG V1. C. Scatterplot for HL60 transfected with KCNRG V2. D. Summary of quadrant totals from scatterplots for HL60 EV, V1, V2.

Cell imaging studies indicated a change of morphology in KCNRG overexpressing cells and generally confirmed FACS findings (Fig.16). The first frames in each set show cells stained with Dioc 18 (red), indicating the membranes of the cells. The second frame in each set show the DAPI (blue) stain, and allows the observation of the nucleus. The third frame in each set shows the rhodamine phalloidin (green) where the actin content of the cell can be observed. The fourth frame in each set is the overlay of all three previous frames, and is a more comprehensive picture of the cells. As can be observed, some cell lines exhibit more dramatic changes than others, most particularly, RPMI-8226 clone

S1B9, isolated from the population of RPMI-8226 stably transfected with KCNRG V1, shows several giant cells with multiple nuclei (Fig. 17 E-H). This phenomenon was also observed in other RPMI-8226 V1 clones, and to a lesser extent, with RPMI-8226 V2 clones (Fig. 17 I-T).

**Fig. 16.** A-D. HL60 vector control cells stained with Dioc18 (red), DAPI (blue), Rhodamine Phalloidin (green), and overlay of all channels. E-H. HL60 cells transfected with KCNRG V1 stained with Dioc18 (red), DAPI (blue), Rhodamine Phalloidin (green), and overlay of all channels. I-L. HL60 cells transfected with KCNRG V2 stained with Dioc18 (red), DAPI (blue), Rhodamine Phalloidin (green), and overlay of all channels.

**Fig. 17.** A-D. RPMI-8226 vector control cells stained with Dioc18 (red), DAPI (blue), Rhodamine Phalloidin (green), and overlay of all channels. E-H. RPMI-8226 V1 - clone S1B9. I-L. RPMI-8226 V1 - clone S2A11 cells. M-P. RPMI-8226 V1 - clone S3A10 cells. Q-T. RPMI-8226 transfected with KCNRG V2 cells.

As can be observed in the LNCaP pictures (Fig.18), cells transfected with either isoform of KCNRG seem to exhibit more extracellular actin content, which may be relevant to their increased contact inhibition. Since LNCaP cells tend to grow in clusters it is difficult to ascertain the presence of multiple nuclei.

**Fig. 18.** A-D. LNCaP vector control cells stained with Dioc18 (red), DAPI (blue), Rhodamine Phalloidin (green), and overlay of all channels. E-H. LNCaP cells transfected with KCNRG V1. I-L. LNCaP cells transfected with KCNRG V2.

Pictures of live cells (Fig.19) provide some visual evidence supporting our notions of the behavior of these cells in culture. Giant multi-nucleated cells lose the ability to divide, and over the course of 2-3 days exhibit membrane blebbing and consequently cell death. Since the cells photographed in fig. 19 are not synchronized, these processes can be seen at various stages.

**Fig. 19.** Live cell pictures for cell lines of HL60, RPMI-8226 and LNCaP.

### **Expression of KCNRG does not influence invasion of LNCaP cells, but affects migration of the suspension cell lines HL-60 and RPMI-8226**

Migration of RPMI-8226 cells stably transfected KCNRG-V2 and KCNRG-V1 as well as vector controls has been studied using  $0.2\text{-}2.0 \times 10^6$  cells/ml and Fetal Bovine

Serum as a chemoattractant. Migration of KCNRG-V1 overexpressing RPMI-8226 cells were not different from that of the control cells, while migration abilities of KCNRG-V2 cells were significantly lower (KCNRG-V2, N=28,  $3.46 \pm 0.408$  vs. Control, N=28,  $2.75 \pm 0.67$ ,  $P < 0.004$ ). Analysis of the transmigration of the vector control and KCNRG overexpressing HL-60 cells through the monolayer of endothelial cell revealed that KCNRG-V1 decreases ability of the cells to penetrate the endothelium (KCNRG-V1, N=5,  $17.19 \pm 0.26$  vs. Control, N=5,  $18.41 \pm 0.59$ ,  $P < 0.01$ ), while overexpression of KCNRG-V2 leads to a non-significant increase in the trans migratory abilities of this cell line. Study of the adherent LNCaP cells revealed that overexpression of the KCNRG isoforms does not influence their ability to cross basement membrane.

Study of anoikis in LNCaP cells showed that both KCNRG overexpressing and vector control cells die upon detachment. Thus there was no influence of KCNRG on anoikis in these cells. An interesting phenomenon that supports observations during routine cell culturing was seen upon imaging of the control plates. Although transfection with either isoform of KCNRG does not change the anoikis behavior of LNCaP cells, cells that are transfected with KCNRG V1 are more prone to contact inhibition, either via other cells, or proximity to the culture vessel walls. This can be observed in the pictures of the control plates for the anoikis assay, where Calcein AM (green) is used to stain live cells and EthD-1 (red) is used to stain cells that have died via anoikis (Fig. 20). All images were taken at the same plate coordinates.

**Fig. 20.** LNCaP cell line anoikis assay. A-D. Anoikis test plate stained with EthD-1 and Calcein AM. E-H. Control plate stained with EthD-1 and Calcein AM.

### **Proteome changes associated with KCNRG overexpression**

To evaluate differences in intracellular molecular networks associated with overexpression of KCNRG, RPA profiling was attempted to assess the changes in the broad spectrum of the cellular signaling events, with emphasis on the phosphorylation and proteolytic events associated with proliferation and apoptosis. In all three cell lines an overexpression of either isoform of KCNRG was associated with decreased activation of mTOR by phosphorylation of Ser 2481 and 2448 and decreased phosphorylation of Tyr 1175 in VEGFR2. In RPMI-8226, overexpression of KCNRG isoforms lead to the coordinated increase of cleavage events in caspases 3,6,7,9 and the caspase target protein PARP. In LNCaP cells, overexpression of KCNRG resulted in a paradoxical profound increase in ERK signaling as revealed by the phosphorylation of Thr 202 and Tyr 204. (See appendix 9 for complete data protein data)

## **Microarray analysis of KCNRG V1**

Analysis of the gene expression profiles was performed using pathway specific single channel microarrays. The first pathway, Oligo GEArray Human Hematopoietic Stem Cells and Hematopoiesis Microarray, consisted of 128 probes; the second pathway, Oligo GEArray ® Human Cancer Microarray, consisted of 480 probes. Comparisons were performed between cells transfected with KCNRG V1 and wild-type cells of the same lineage. The Superarray software analysis platform offers three standard methods of normalization of arrays, “to the mean”, “to the median” and “to the values for the set of the selected genes”. Traditionally, housekeeping genes have been employed as endogenous reference (“selected genes”) genes for normalization in gene expression studies.

Unfortunately, for most of the housekeeping genes the variability in expression is significant between different cell lines, despite the equalization of quantities of input RNA (Aerts JL et al. 2004). The importance of this phenomenon is most prominent in case of studies of cancer cells and their phenotypes, as profound changes occur in even the most basic metabolism of the cell as it becomes malignant (Gillies RJ et al., 2008). For example, GAPDH and ACTB, genes most frequently used for normalization, are heavily regulated during carcinogenesis and tumor progression (Aerts J.L. et al., 2004; Gao Q. et al., 2008; Lyng MB et al., 2008). These findings are not surprising as recent evidence indicates new and intriguing roles for GAPDH in fundamental mammalian cell processes, including DNA repair, translational control of gene expression, DNA replication and endocytosis (Sirover et al. 2006).

Since the utilization of single housekeeping gene cannot assure an unbiased result, finding a good set of reference genes is a non-trivial problem requiring case-by-case study. Here we tested housekeeping genes against the overall intensity of the array, and a subset indicative of each array was selected for normalization. Figure 21 shows the topographic map of the housekeeping gene expression across all arrays.

**Fig. 21.** Topographic map of housekeeping genes and their behavior in all arrays. RR = RPMI Control, HR = HL60 Control, LR = LNCaP control, RT = RPMI transfected, HT = HL60 transfected, LT = LNCaP transfected.

In addition to their expression pattern, housekeeping genes were selected based on their ability to correctly reflect the overall intensity of their representative arrays. Background correction was performed by the SuperArray proprietary software, and

normalized versus non-normalized values for blank controls, overall array intensities and selected housekeeping genes were determined (Fig.22).

**Fig. 22.** Effects of normalization on selected genes (housekeeping genes), blanks and array average.

Following background correction and normalization, spreadsheets displaying fold differences between control cases and test cases were generated (for complete lists of differentially expressed genes present on each array please see Appendix r). Initially, statistical analysis was performed by the Significance Analysis of Microarrays (SAM), a popular method for detecting significantly expressed genes and controlling the false discovery rate (FDR) (Rodniger OK et al., 2005; Tusher et al., 2001). False discovery rate (FDR) is defined as the expected percentage of false positives among all the claimed positives. Calculations were performed with the much appreciated help of G. Manyam (PhD student, MMB, GMU). However, recent opinion on statistical testing for small batch microarrays seems to be moving away from permutation based approaches such as SAM (Tan YD et al. 2008). The consensus seems to be that these permutation based approaches often create data sets with very heavy tails, and negatively biased data. Hence

a non-parametric Mann-Whitney test was used for the statistical validation of the microarray data.

In addition to spot finding and numerical value assignation, the SuperArray software sorts each spot as “absent” or “present” based on the intensity of its immediate background environment. This proved problematic in some cases due to over saturation in adjacent spots, as the parameters for this function are non-negotiable; consequently we believe that some spots were mislabeled as absent. The resultant genes from both arrays were compiled and a list with the most significant p-values was created (See Fig 23).

Cell line & change	RR negative change	RR positive change	HR negative change	HR positive change	LR negative change	LR positive change

**Fig. 23.** List of Mann-Whitney significant genes compiled from microarray experiments.

Although all three cell lines responded similarly to transfection with KCNRG isoforms, i.e., a general trend of increased apoptosis and decreased proliferation, very few genes seem to be up- or down-regulated in the same direction in all three cell lines, possibly indicating very different expression pathways involved in the proliferation and apoptosis in each type of cell. HSPA5, one of the few genes that is up-regulated in both HL60 and RPMI cells, is a member of the heat-shock protein-70 (HSP70) family. It is thought to aid in protein assembly in the endoplasmic reticulum and may play a role in protein transport in the cell (GeneCard). Conversely, TK1, a cytosolic thymidine kinase known to have a high activity in rapidly proliferating cells and very low activity in resting cells, was down-regulated in both HL60 and LNCaP cells.

The BAX gene behaves differently in HL60 cells as compared to LNCaP and RPMI-8226 cells. BAX functions as a pro-apoptotic gene by forming a heterodimer with BCL2 and is thought to interact with mitochondrial voltage-dependent anion channels (VDAC), causing a loss in membrane potential and thereby releasing Cytochrome C. BAX is thought to be regulated by the p53 tumor suppressor protein (Fig. 24).

Surprisingly, HL60 cells show a down-regulation of BAX, whereas RPMI-8226 and LNCaP cells show a marked up-regulation of BAX in keeping with the more classical model of BAX-mediated apoptosis. None of the cell lines show any change in BCL2 levels, although LNCaP cells seem to have a drastically lower amount of native BCL2 expression.

## Independent and array based RT-PCR profiling of genes from microarray

Sixteen genes with the highest degree of commonality were selected from the microarray short list to be verified by RT-PCR. The results of the RT-PCR were compared to those of the microarrays (Fig. 25).

Fig. 25. RT-PCR validated genes selected from microarray short list

In addition to validating the microarray data the apparent discrepancies between the microarray data and RT-PCR data needed to be analyzed further. The oligonucleotide sequences used by SuperArray are proprietary, hence the exact sequences are not available for this work and they could not be matched to a particular area of the corresponding transcript. The BAX oligonucleotide used as a probe for the Superarray was designed by the manufacturer to identify only two out of five BAX isoforms. To see whether this could account for part of the discrepancy two separate BAX primers were used: BAX 430 and BAX 225, designed to amplify BAX transcript variant beta and

alpha, respectively (see Appendix 11). The two BAX variants were found to behave in a very different fashion in HL60 cells transfected with KCNRG V1 (Fig 26).

**Fig. 26.** RT-PCR validated genes selected from microarray short list, zoom on HV1 and BAX primers for BAX isoforms alpha and beta.

This behavior suggests the possibility that some of these unresolved disagreements between RT-PCR data and microarray data may be due to microarrays and RT-PCR profiling different isoforms of the mRNA for a particular gene.

To further confirm the microarray data, a set of SuperArray RT-PCR arrays were performed. The Human Apoptosis pathway RT-PCR array was chosen based on the number of overlapping genes found between the RT-PCR and microarray platforms. Once again the manufacturer did not disclose the primers present on the RT-PCR array, however, the manufacturer did disclose that these primers bore no similarities to the sequences found on the microarray and were not guaranteed to isolate the same isoforms of the genes. Keeping this in mind, the 18 genes in common to both platforms, and 2/3 of these agreed in the direction of change (For full results see Appendix 11). In the case of

HL60 cells, a large percentage of genes were in agreement according to the directionality of gene expression changes (Table 3).

**Table 3.** SuperArray RT-PCR and Oligo Array results compiled.

Interestingly, there are small but significant changes in expression between HL60 cells transfected with KCNRG V1 versus KCNRG V2. In a significant number of cases, the effects of KCNRG V1 on gene expression profiles were more dramatic than the effects of KCNRG V2.

## Real-time PCR profiling of KCNRG mRNAs in human lymphoma samples

Relative levels of KCNRG isoforms were quantified in human lymphoma samples arrayed on TissueScan qPCR Panels (Fig. 27) As expression of the major isoform of KCNRG mRNA encoding KCNRG V1 was approximately 300 times higher than that of the minor mRNA isoform (KCNRG V2), estimates of the mRNA levels obtained using primer pair KCNRG V1/V2 can be approximated to the expression of KCNRG-V1 encoding isoform.

**Fig. 27.** Real-time PCR profiling of KCNRG mRNAs in human lymphoma samples. N: Normal PBL. FL: follicular lymphoma. DLBL: diffuse large B-cell lymphoma. SLL: small lymphocytic lymphoma. HL: Hodgkin lymphoma. MZBL: marginal zone B-cell lymphoma. MCL: mantle cell lymphoma. TL: T-cell lymphoma. A and B: profiling using primer pair KCNRG-V1/V2 that amplifies both isoforms of KCNRG mRNA. C and D: profiling using primer pair KCNRG V2 that amplifies only mRNA isoform KCNRG V2. Statistically significant changes denoted by star (\*) symbol.

Significant down regulation of KCNRG-V1 mRNA ( $P < 0.05$ ) was revealed in the most advanced lymphomas of the stage IV ( $N = 4$ ) as compared to normal PBL samples ( $N=6$ ). When the same set of samples were stratified according to the type of lymphoma, a significant down-regulation of KCNRG V1 was registered only in DLBL ( $N=11$ ) as compared to normal PBL samples ( $P < 0.002$ ).

Interestingly, only one case of DLBL was classified as a stage IV disease, while 6 of these cases were stage I and 4 were staged as IE or IIE. A trend towards down-regulation of the KCNRG V2 encoding mRNA was seen in all lymphoma types profiled, with statistically significant differences seen in FL ( $P < 0.002$ ), DLBL ( $P < 0.02$ ) and T-cell lymphoma ( $P < 0.03$ ) groups. A significant decrease in the level of mRNA for KCNRG V2 was seen in stage I ( $P < 0.008$ ) and IIE ( $P < 0.04$ ) groups.

## **Chapter 4: Conclusion**

Previous studies of the tumor suppressor effects conveyed by the presence of intact chromosome 13 region q14.3 revealed a number of potential candidate genes whose expression is lost in a substantial percentage of CLL cases. Despite significant effort undertaken by multiple laboratories a screening of the mutations in the studied candidate genes in primary tumor cells has not yet been successful. These findings prompted some investigators to propose that a major mode of inactivation of 13q14 tumor suppressor gene(s) is by the deletion of one copy of the gene causing decrease in the production of gene' mRNA and partial loss of its function. This mechanism of gene inactivation is known as haploinsufficiency.

Candidate TSG KCNRG (potassium channel regulating gene) is located very close to the 10-kb region previously described as minimally deleted in CLL and within the larger region deleted in the majority of CLL cases with 13q14.3 aberrations.

Functional analysis of KCNRG pointed at the possibility that it might exert a tumor suppressor effect relevant to CLL and MM. Here KCNRG has been shown to possesses anti-proliferative activity when overexpressed in RPMI-8226, HL-60 and to a lesser extent, LNCaP cells. Moreover, overexpression of KCNRG stimulates apoptosis in these cells and leads to dramatic changes in their size and shape. A substantial proportion

of both RPMI-8226 and HL-60 cells over expressing KCNRG V1 isoform were arrested in G2 phase, possibly indicative of G2/M checkpoint activation.

Additionally, the migration of KCNRG overexpressing cells has also significantly decreased. Microarray and RT-PCR data, taken together with the proliferation and caspase assays, suggests that these events may be occurring via different mechanisms for each cell line, possibly indicating a broader, rather than a pathway specific, role for KCNRG. Finally, KCNRG overexpression increased a propensity of the cells to undergo apoptosis after stress, in particular, affecting its ability to recover after storage in a frozen state.

One way to confirm the relevance of these characteristics of human KCNRG in the suppression of CLL and MM *in vivo* is to find its point mutations in primary tumor cells. Attempts to do so by this lab as well as others have been unsuccessful. However, a number of circumstantial evidence points at KCNRG as an important player in hematological malignancies. First, real-time PCR profiling of KCNRG mRNAs revealed that levels of the major isoform of KCNRG mRNA in DLBL lymphomas are lower compared to normal PBL samples, while levels of its minor mRNA decreased across the broad range of the lymphoma types.

Levels of KCNRG mRNA were also decreased in lymphomas of stage IV. Second, the multiple myeloma cell line RPMI-8226 contains a delT mutation in the core promoter initiator element that might influence levels of KCNRG expression in this model line. Third, proteomics endpoint analysis by RPA indicated an involvement of KCNRG in the suppression of mTOR and VEGFR pathways as well as in caspase

activation in a broad sense. In light of these observations, the identification of the particular mode of KCNRG inactivation in tumor samples becomes a priority.

Despite a number of studies that delineated 13q14 deletions in CLL and MM and quantified relative expression levels of some candidate genes residing in this area, the critical insights related to the role of 13q14 in human malignancies are still to be gained. Here in this work is described a novel, highly informative polymorphic repeat, located at the position –1006 relative to the major start of KCNRG mRNAs and within the 3' untranslated area of RFP2. As the structure of this repeat allows its relatively simple visualization in agarose gels following conventional PCR, it might become a valuable marker for the hemizygous deletion of KCNRG in primary tumor samples.

Interestingly, KCNRG belongs to a rather large subfamily of poorly characterized human genes. Some of these genes function in tumorigenesis. As cellular functions for the majority of the KCNRG-like proteins have never been studied, it is important to determine their relevance to tumorigenesis and lymphomagenesis in humans.

In conclusion, a functional study of the tumor suppressor gene candidate KCNRG was conducted and its growth suppressive and pro-apoptotic effects in the cellular models relevant to CLL and MM was demonstrated. This study demonstrates that the loss of KCNRG might be relevant to the progression of these hematological malignancies at least in a subset of the patients with these disorders.

## ■ Globular domains/ TM domains and signal peptide detected by the **SMART** server

## ■ Results of ELM motif search after globular domain filtering and context filtering.

All matches falling inside SMART/PFAM domains are excluded from this list.

Elm Name	Elm Description	Cell Compartment	Pattern
<u>LIG_FHA_1</u>	FHA domain interaction motif 1, threonine phosphorylation is required	nucleus, plasma membrane, cytosol	T..[ILA]
<u>LIG_PDZ_3</u>	Class III PDZ domains binding motif	membrane, plasma membrane, cytosol	.[DE].[IVL]
<u>LIG_PTAP</u>	PTAP alike ligands	not annotated	P[TS]AP
<u>LIG_SH3_2</u>	this is the motif recognized by class II SH3 domains	plasma membrane, focal adhesion, cytosol	P..P.[KR]
<u>LIG_SH3_3</u>	This is the motif recognized by those SH3 domains with a non-canonical class I recognition specificity	plasma membrane, focal adhesion, cytosol	...[PV]..P
<u>LIG_WW_4</u>	Class IV WW domains interaction motif; phosphorylation-dependent interaction.	nucleus, cytosol	...[ST]P.
<u>MOD_CK1_1</u>	CK1 phosphorylation site	nucleus, cytosol	S..([ST])...
<u>MOD_GlcNHglycan</u>	Glycosaminoglycan attachment site	extracellular, Golgi apparatus	D][0,3).(S)[GA].

## ■ List of excluded ELMs falling inside SMART/PFAM domains.

Matches in this list are only likely to be of interest if they are in surface-exposed loops.  
Consult the [SMART](#) or [PFAM](#) entries for useful links to solved 3D structures.

Elm Name	Elm Description	Cell Compartment	Pattern
<a href="#">CLV_PCSK_SKI1_1</a>	Subtilisin/kexin isozyme-1 (SKI1) cleavage site ([RK]-X-[hydrophobic]-[LTKF]-X)	Golgi apparatus, endoplasmic reticulum lumen, endoplasmic reticulum	.ILMFV[.][LTKF].
<a href="#">LIG_CYCLIN_1</a>	Substrate recognition site that interacts with cyclin and thereby increases phosphorylation by cyclin/cdk complexes. Predicted protein should have the MOD_CDK site. Also used by cyclin inhibitors.	nucleus, cytosol	[0,1]{FYLVIMP}
<a href="#">LIG_FHA_1</a>	domain interaction motif 1, threonine phosphorylation is required	nucleus, plasma membrane, cytosol	T..[ILA]
<a href="#">LIG_NRBOX</a>	The nuclear receptor box motif (LXXLL) confers binding to nuclear receptors.	nucleus	P[.[^P](L)(L)[^P]
<a href="#">LIG_PDZ_3</a>	Class III PDZ domains binding motif	membrane, plasma membrane, cytosol	.[DE].[IVL]
<a href="#">LIG_SH2_STAT3</a>	YXXQ motif found in the cytoplasmic region of cytokine Receptors that bind STAT3 SH2 domain.	not annotated	Y..Q
<a href="#">LIG_SH2_STAT5</a>	STAT5 Src Homology 2 (SH2) domain binding motif.	not annotated	Y[VLTFIC]..
<a href="#">LIG_TRAF2_1</a>	Major TRAF2-binding consensus motif. Members of the tumor necrosis factor receptor (TNFR) superfamily initiate intracellular signaling by recruiting the C-domain of the TNFR-associated factors (TRAFs) through their cytoplasmic tails.	cytosol	[PSAT].[QE]E
<a href="#">LIG_TRAF6</a>	TRAF6 binding site. Members of the tumor necrosis factor receptor (TNFR) superfamily initiate intracellular signaling by cruiting the C-domain of the TNFR-associated factors (TRAFs) through their cytoplasmatic tails.	cytosol	.E..[FYWHDE].
<a href="#">MOD_PKA_2</a>	PKA phosphorylation site	cytosol	.R.([ST])...
<a href="#">RG_ENDOCYTIC_2</a>	Tyrosine-based sorting signal responsible for the interaction with mu subunit of AP (Adaptor Protein) complex	plasma membrane, clathrin-coated endocytic vesicle, cytosol	Y..[LMVIF]
<a href="#">LysEnd_APsAcLL_1</a>	Sorting and internalisation signal found in the cytoplasmic juxta-membrane region of type I transmembrane proteins. Targets them from the Trans Golgi Network to the lysosomal-endosomal-melanosomal compartments. Interacts with adaptor protein (AP) complexes	Endocytic vesicle, cytosol	[DER]...L[LVII]

## CURRICULUM VITAE

Aybike Birerdinc graduated from the International School of Islamabad, Islamabad, Pakistan, in 1994. She received her Bachelor of Science from Trinity College in 1999, and received her Master of Science in Biochemistry with a specialization in Biotechnology from Georgetown University in 2001.
